## CONTRIBUTORS TO VOLUME III

- Herbert A. Aikins**, Ph.D., LL.D., Professor of Philosophy, Western Reserve University. (*David Hume.*)
- Roswell P. Angier**, Ph.D., Assistant Professor of Psychology and Acting Director of the Psychological Laboratory, Yale University. (*Topics in Psychology.*)
- Joseph Cullen Ayer, Jr., Rev.**, Ph.D., Professor of Ecclesiastical History, Divinity School, Protestant Episcopal Church, Philadelphia, Pa. (*Topics in Early Christian and Medieval Education.*)
- Liberty H. Bailey**, LL.D., Director of New York State College of Agriculture, Cornell University. (*Horticulture.*)
- Franklin T. Baker**, Litt.D., Professor of English Language and Literature, Teachers College, Columbia University. (*English Language, etc.*)
- Maurice A. Bigelow**, Ph.D., Professor of Biology, Teachers College, Columbia University. (*School Gardens.*)
- Franz Boas**, Ph.D., LL.D., Professor and Head of Department of Anthropology, Columbia University. (*Growth.*)
- Henry E. Bourne**, Ph.D., Professor of History, Western Reserve University. (*History*)
- Edward F. Buchner**, Ph.D., Professor of Education and Philosophy, Johns Hopkins University. (*Educational Philosophers.*)
- William H. Burnham**, Ph.D., Professor of Pedagogy and School Hygiene, Clark University. (*Topics in School Hygiene*)
- Edward H. Cameron**, Ph.D., Associate Professor of Psychology, Yale University. (*Topics in Psychology.*)
- Thomas C. Chamberlain**, Ph.D., LL.D., Professor and Head of the Department of Geology; Director of Museums, University of Chicago. (*Geology.*)
- Percival R. Cole**, Ph.D., Vice-Principal of the Training College, Sydney, Australia. (*Herbart.*)
- Gabriel Compayré**, Inspector General of Public Instruction; Member of the Institute of France. (*Education in France.*)
- G. G. Coulton**, Late Birkbeck Lecturer in Ecclesiastical History, University College, Cambridge. (*Hall or Hostel.*)
- Ellwood P. Cubberley**, Ph.D., Professor of Education, Leland Stanford Jr. University. (*Educational Administration; State Systems of Education.*)
- Alexander Darroch**, M.A., Professor of Education, University of Edinburgh. (*Scotch Universities and Biographies.*)
- Henry Davies, Rev.**, Ph.D., Rector, Easton, Md. (*Educational Philosophers.*)
- Walter F. Dearborn**, Ph.D., Assistant Professor of Psychology, Harvard University. (*Topics in Psychology.*)
- John Dewey**, Ph.D., LL.D., Professor of Philosophy, Columbia University. (*Topics in Philosophy of Education.*)
- Richard E. Dodge**, A.M., Professor of Geography, Teachers College, Columbia University. (*Geography.*)
- Fletcher B. Dresslar**, Ph.D., Expert in School Hygiene, U. S. Bureau of Education, Washington, D.C. (*Topics in School Hygiene.*)
- Knight Dunlap**, Ph.D., Associate in Psychology, Johns Hopkins University. (*Psychological Topics.*)
- Charles A. Eastman**, M.D., Amherst, Mass. (*American Indians.*)
- Roland P. Falkner**, Ph.D., Assistant Director, Bureau of the Census, Washington, D.C. (*Immigration and Education.*)
- Aristide Fanti**, Librarian, United States Bureau of Education, Washington, D.C. (*Education in Italy.*)
- Frederic E. Farrington**, Ph.D., Associate Professor of Educational Administration, Teachers College, Columbia University. (*French Educators.*)
- Lee K. Frankel**, Assistant Secretary Metropolitan Life Insurance Company, New York City. (*Educational Work of Insurance Companies.*)
- Fabian Franklin**, Ph.D., LL.D., Associate Editor *Evening Post*, New York City. (*D. C. Gilman.*)
- Shepherd I. Franz**, Ph.D., Scientific Director and Psychologist, Government Hospital for the Insane; Professor of Experimental Psychology and of Philosophy, George Washington University. (*Topics in Psychology.*)
- H. B. Frissell**, D.D., LL.D., Principal, Hampton Normal and Industrial Institute, Hampton, Va. (*Hampton Institute.*)

## CONTRIBUTORS TO VOLUME III

- Charles Galwey**, A.B., Tutor of English, College of the City of New York. (*Colleges and Universities.*)
- Thomas D. Goodell**, Ph.D., Professor of Greek, Yale University. (*Study of Greek; Homer.*)
- Willystine Goodsell**, Ph.D., Assistant Professor of the History of Education, Teachers College, Columbia University. (*Infant Education.*)
- William E. Griffis**, D.D., L.H.D., Ithaca, N.Y. (*Korea; Japan.*)
- Louis Grossmann**, Ph.D., Principal, Hebrew Union College, Cincinnati, O. (*Jewish Education.*)
- Charles H. Haskins**, Ph.D., Professor of History and Dean of the Graduate School, Harvard University. (*History*)
- Ernest N. Henderson**, Ph.D., Professor of Philosophy and Education, Adelphi College (*Topics in Philosophy and Psychology.*)
- Milo B. Hillegas**, Ph.D., Assistant Professor of Elementary Education, Teachers College, Columbia University. (*Education in Modern Greece*)
- Douglas Hyde**, LL.D., D.Litt., Dublin, Ireland. (*Education in Ireland*)
- Torstein Jahr**, Cataloguer, Library of Congress, Washington, D.C. (*Greenland.*)
- Joseph Jastrow**, Ph.D., Professor of Psychology, University of Wisconsin. (*Hypnosis*)
- G. E. Johnson**, A.M., Superintendent, Pittsburgh Playground Association, Pittsburgh, Pa. (*Games.*)
- Wm. Dawson Johnston**, Litt.D., Librarian of Columbia University. (*Libraries.*)
- Charles H. Judd**, Ph.D., LL.D., Professor and Director of the School of Education, University of Chicago. (*Topics in Educational Psychology.*)
- Isaac L. Kandel**, Ph.D., Teaching Fellow in Teachers College, Columbia University. (*Topics in Educational History and Administration*)
- Ikuchi, D.**, Baron, Member of Privy Council, Tokyo. (*Education in Japan.*)
- William H. Kilpatrick**, Ph.D., Assistant Professor of the History of Education, Teachers College, Columbia University. (*Topics in the History of Education*)
- Helen Kinne**, Professor of Household Arts Education, Teachers College, Columbia University. (*Kitchen Garden. Household Art in Education.*)
- George W. Kirchwey**, LL.D., Kent Professor of Law, Columbia University. (*Legal Education*)
- George P. Krapp**, Ph.D., Professor of English, Columbia University. (*Grammar; Languages, Artificial, Language, English; Literature, English.*)
- Cecil F. Lavell**, Ph.D., Assistant Professor of the History of Education, Teachers College, Columbia University. (*Greek Education.*)
- Arthur F. Leach**, Charity Commissioner for England and Wales, London. (*Topics in English Educational History.*)
- James G. Legge**, Director of Education, City of Liverpool. (*Industrial Education*)
- Florence N. Levy**, Editor, *American Art Annual*. (*Industrial Art Schools.*)
- Samuel M. Lindsay**, Ph.D., LL.D., Professor of Political Science, Columbia University. (*Juvenile Delinquency, etc.*)
- Gonzalez Lodge**, Ph.D., LL.D., Professor of Latin and Greek, Teachers College, Columbia University. (*Latin Language and Literature*)
- Arthur O. Lovejoy**, A.M., Professor of Philosophy, Johns Hopkins University. (*G. M. Leibnitz*)
- Joseph McCabe**, formerly Rector of Buckingham College. (*Hypatia.*)
- Roswell C. McCrea**, Ph.D., Professor of Economics, University of Pennsylvania (*Humane Education*)
- Millicent Mackenzie**, M.A., Professor of Education, University College, Cardiff, Wales (*Hegel*)
- John P. Mahaffy**, D.D., Trinity College, Dublin, Ireland. (*Greek Education.*)
- George L. Meylan**, M.D., Assistant Professor of Physical Education and Medical Director of the Gymnasium, Columbia University. (*Educational Athletics, etc.*)
- Paul Monroe**, Ph.D., Professor of the History of Education, Teachers College, Columbia University (*Topics in the History of Education*)
- Will S. Monroe**, A.B., Professor of Psychology and Education, State Normal School, Montclair, N.J. (*American Biography, etc.*)
- Frederick Montser**, Ph.D., Head of German Department, De Witt Clinton High School, New York City; formerly Lecturer on Education, New York University (*German Educational Biography*)
- J. E. G. de Montmorency**, B.A., LL.B., Library Editor of *The Contemporary Review*; Barrister, London, England. (*Topics in English Educational History.*)

## CONTRIBUTORS TO VOLUME III

- H. Kingsmill Moore**, Rev., Kildare Place, Dublin, Ireland. (*Education in Ireland.*)
- James Bass Mullinger**, M.A., Litt D, Librarian and Lecturer in History, St. John's College, Cambridge University. (*Greek, Study of.*)
- Wilhelm Münch**, Ph.D., Late Geheim-Regierungsrat and Ordentlicher Honorar-Professor of Education, University of Berlin. (*Education in Germany*)
- Naomi Norsworthy**, Ph.D., Associate Professor of Educational Psychology, Teachers College, Columbia University. (*Infant Education*)
- William Orr**, Deputy Commissioner, State Board of Education, Boston, Mass. (*High School Fraternities*)
- Jean Phillipe**, Ph.D., Associate Director of the Laboratory of Physiological Psychology, Sorbonne, Paris. (*Greard; French Journals and Journalism*)
- Walter B. Pillsbury**, Ph.D., Professor of Psychology, University of Michigan. (*Topics in Psychology.*)
- Alice Ravenhill**, Formerly Inspector of Hygiene and Domestic Economy, West Riding, Yorkshire. (*Household Arts*)

# A CYCLOPEDIA OF EDUCATION

**GAILHARD, JOHN** — Writer of the *Complete Gentleman*, 1678. This treatise is divided into two parts, the first containing directions for the education of youth, in their breeding at home, and the second concerns itself with their breeding in traveling abroad. Gailhard seems to have spent a number of years as tutor abroad to "several of the nobility and gentry." In the first part, he treats of breeding children at home, and recommends a wide curriculum similar to that of Milton. Throughout the stress is laid upon the bearing and breeding and character which should be shown by the nobleman and the best means of inducing it.

In the next part, Gailhard points out the qualifications, duties, and value of the traveling tutor, and his treatise is probably the most complete on the subject. Before traveling, the pupil should learn something of the language of the country to which he goes. He should, too, know well his own country and its main characteristics before traveling. The pupil, following the excellent custom noted by Bacon, is to "take pains in writing in his Diary Book" all he sees. Religious devotions and reading of the Bible must not be neglected. Physical exercises and music must also receive attention. If he comes to a convenient place, he should learn the general principles of physic, say at Padua or Montpellier, and Civil Law, say at Angers or Orleans. Drawing should also be learned. Gailhard suggests three years as the time for the Grand Tour, of which half should be spent in France. On the whole, Gailhard's book gives great insight into the tone and standards of the young gentleman of the times and the current English views of foreign nations. F. W.

See GENTRY AND NOBLES, EDUCATION OF

**GALE, GEORGE WASHINGTON** (1789-1863). — A pioneer in the movement for manual training in the United States, was graduated from Union College in 1814 and from the Princeton Theological Seminary in 1818. He was for several years engaged in the work of the ministry; but, failing in health, he retired to a farm at Whitesboro, N. Y., where he gave a class of boys free board and tuition for a few hours of work each day on the farm. Out of the experiment grew the Oneida Manual Labor Institute of which he was principal for seven years (1827-1834). Courses were given in applied agriculture and woodwork. He was one

of the founders of Knox College at Galesburg, Ill., and for a few years a professor there.

**GALE COLLEGE, GALESBURG, WIS** — See LUTHERAN EDUCATIONAL SYSTEM IN THE U. S.

**GALEN, CLAUDIUS** (131-c. 201). — Greek physician and writer on medical subjects. He was born at Pergamon in the reign of Hadrian. Galen studied medicine at Pergamon, Smyrna, and Alexandria. On completing his studies he returned to his native city where he was appointed physician to the athletes in the gymnasium. He spent a few years at Rome, where his ability attracted attention. In 169 he was summoned to attend the Emperors Marcus Aurelius and L. Verus in the campaign on the north-eastern frontier. He returned to Rome, where he became for a time physician to Aurelius and Commodus. The exact date of his death is not known, but Galen certainly lived in the reign of Septimus Severus.

Galen was a prolific writer and is credited with some 500 works. Of the extant works about 118 are considered to be genuine. Although known mainly by his medical works, he wrote many treatises on philosophy and literary criticism. Among his writings are commentaries on the dogmas of Plato and on the *Timæus*. His interest in the works of Hippocrates is shown by the commentaries. He also wrote on the Ancient Comedy, on Atticisms, and on style. But his fame rests on his works in the field of medicine. He touched on every aspect of the subject, including anatomy and physiology, dietetics and hygiene, pathology, diagnosis, pharmacy, and materia medica, therapeutics, and surgery. He treats of the anatomical phase most successfully, although it is not thought that he had any opportunities for dissecting human bodies. He himself recommended the dissection of animals, and especially monkeys, as being most like the human being. He is reputed to have performed some remarkable surgical operations. In the field of pharmacy and materia medica he seems to have had more faith in amulets than in medicine, although he was famous for certain prescriptions. Galen was the first and greatest authority on the pulse.

Galen's works held the place in the study of medicine in the medieval universities which Aristotle held in philosophy. His authority was not questioned until the sixteenth century. In 1559 a Dr Geyner was admitted to the College of Physicians of England only on recanting his attacks on the infallibility of Galen. But from the time of Galen all sects (*c q* Dogmatics, Empirics, Eclectics, Pneumatics, and Episynthetics) were united under the one great source of medical lore. His works were for a long time read in Latin or Arabic translations. The first edition of the Greek text was published by the Aldine press in 1525.

**GALILEI, GALILEO** (1564-1642).—The famous astronomer was born at Pisa. His father, who was skilled in music and mathematics, intended the son for trade, but was prevailed upon to send him to the University of Pisa to study medicine. Galileo was of such an argumentative disposition that he won for himself the nickname of "the wrangler." But his bent was not for medicine. In 1582 he made his first scientific discovery of the principle of oscillation of a pendulum and invented an instrument which was useful to doctors in testing the beat of the pulse. Through poverty he was compelled to leave the University without a degree in 1585. In 1586 he wrote an essay, not published until the last century, on the hydrostatic balance, an instrument which he had invented to measure the specific gravity of solids. In 1589 he became professor of mathematics and astronomy in the University of Pisa. At this period began his long series of experiments which mark the beginning of modern methods in scientific study. In place of deductions and reliance on the authority of Aristotle he made actual experiments as precise as they could be in his time. He devoted his attention to a study of falling bodies, and concluded, contrary to the opinion of the day, that the time taken by falling bodies depended not on their weight, but on the resistance of the air. Although the appointment at Pisa was for three years, he left before his time expired, owing to the attacks of his opponents. In 1592, he was appointed professor of mathematics at Padua, originally for a period of six years, later gradually extended to eighteen years, and then for life. Here he attracted large audiences to his lec-

tures, and devoted his attention to mechanics and the invention of scientific instruments. His first discovery of importance in astronomy was made in 1604 when he noticed the appearance of a star in the constellation Serpentarius which was more distant than the planets. From this period on Galileo's reputation was spread over Europe by his telescopic observations, and his improvements on the telescope. His discoveries he published in 1610 in *Sidereus Nuncius* (*Sidereal Messenger*). Here he showed that the markings on the moon were caused by mountains and their shadows, that the moon was much like the earth, and that celestial phenomena were similar to those on the earth. The Pleiades and the Milky Way he proved to consist of numerous stars invisible to the naked eye. In the same year he discovered the Satellites of Jupiter. Feeling the need of more time for his researches and writing, he returned to Pisa, where he was appointed professor of mathematics and first philosopher and mathematician to the Grand Duke of Tuscany, a well-salaried post with few duties attached. Among his other discoveries were the sun spots and the fact that Venus derived light from another body in the same way as the moon.

There were not wanting those who seized an opportunity of assailing Galileo for his overthrow of the belief in the celestial bodies as perfect and unchangeable. He was drawn into a dispute on the question of the validity of reasoning and observation on the one hand, and scriptural and ecclesiastical authority on the other. His attitude is illustrated by the following quotation from his writings, "Methinks, that in the discussion of natural problems we ought not to begin at the authority of places of scripture, but at sensible experiments and necessary demonstrations." In 1615 he was denounced to the Inquisition which appointed a body of theologians to examine the Copernican doctrines, as a result Galileo was admonished by order of the Pope to abandon his opinions. For the next few years Galileo remained in Rome, where he had powerful friends. In 1623 he wrote *Il Saggiatore* (*The Assayer*), the final contribution to a controversy on which he had entered with a Jesuit in 1618. The book again brought him into favor with the Pope, to whom it was dedicated. In 1632, after considerable difficulties with the censors at Rome and Florence, he published a Dialogue on the *Two Chief Systems of the World, the Ptolemaic and Copernican*, which was a powerful argument in support of the Copernican theory set out in a thinly veiled disguise. A feeling that the book treated disparagingly of the Pope caused the Inquisition to stop the sale of the book and to compel Galileo to appear for trial. He was treated kindly during the trial, but was condemned to prison. Through the influence of his friends he was allowed to remain in confinement in a country house near Florence. He

continued his investigations, which, however, were cut short by blindness in 1636. The chief work of this period was *Mathematical Discourses and Demonstrations concerning Two New Sciences, relating to Mechanics and to Local Motion*, written in the form of a dialogue and dealing with statics, falling bodies, and projectiles. In 1642 Galileo died and was buried in the Cathedral of Santa Croce. Galileo ranks with Bacon as one of the founders of modern experimental science. In astronomy he will always have a permanent place, for many of his discoveries, despite the lack of exact instruments, were remarkable for their precision. In dynamics he created an entirely new science which served as a basis on which future scientists were to build.

**GALL, FRANZ JOSEPH** (1758-1828).—The founder of phrenology (*q.v.*), born at Tiefenbrunn in Baden, the son of an Italian merchant named Gallo. He received his early education at the hands of his uncle, a Catholic priest; later studied at Baden, at Bruchsal, at Strassburg, where he distinguished himself by research in natural history, and at Vienna, where he took his doctoral degree and commenced the practice of medicine. In 1796 he began to promulgate his theory in lectures, which were continued until 1802, when they were forbidden by the Austrian government as inimical to religion. In 1805 he left Vienna, in company with his pupil Spurzheim, and in 1807 established himself at Paris. In the intervening two years he lectured in the principal cities of northern and central Europe, and in 1823 delivered a few lectures in London. He continued lecturing at Paris until a few months before his death, which occurred at Montrouge.

The observations on which Gall based phrenology began during his boyhood, with the noticing of an apparent relation between the size of the eye and the retentiveness of memory. At Strassburg and Vienna Gall was indefatigable in the examination of the heads of persons who exhibited striking mental peculiarities, modeling many of them in plaster and wax; and extended his study to the lower animals. He was practically the first to recognize the main features of the gross anatomy of the brain, and the function of the fibers and of the cortex. The importance of his work is indicated by one of the inscriptions on a medal struck in his honor in Berlin: *Il trouva l'instrumente de l'âme*. Gall's most important publications

were the *Recherches sur le système nerveux en général et sur celui du cerveau en particulier*, written in collaboration with Spurzheim (*q.v.*), and published in 1809; and the *Anatomie et physiologie du système nerveux*, which appeared in four volumes in 1810-1819. The latter work was commenced with Spurzheim, but finished alone, the two having quarreled and separated. An abridged edition was published by Gall in 1822, and an English translation appeared in Boston in 1835. K. D.

**GALLAUDET, THOMAS HOPKINS** (1787-1851).—The founder of the first American school for the deaf, born in Philadelphia the 10th of December, 1787. He received his education at the Hartford Grammar School, Yale College (graduating in 1805), and Andover Theological Seminary. Becoming interested in the deaf, and recognizing their need of education, he went to England to study the methods of lip-reading and articulation in use in that country. The selfishness of the proprietors of the British schools made it impossible for him to study the methods there used, and he went to Paris, where he was cordially received by the Abbé Sicard (*q.v.*), who placed all the facilities of the French institution at his disposal. The manual or sign method was employed in the Paris school, and this was the method that Gallaudet brought to America. With the assistance of Laurent Clerc, who had been associated with the Abbé Sicard, Gallaudet organized the American Asylum for Deaf-mutes at Hartford, in 1816, and continued at its head until 1830. As this was the first school for the deaf in the United States, practically all the instructors in deaf schools in the country for a half century were trained at Hartford, and the manual or sign alphabet became the dominant method of instruction. During 1832 and 1833 Gallaudet was professor of the philosophy of education in New York University. This was the first professorship of education in the United States. (See EDUCATION, ACADEMIC STUDY OF.) He was also active in the movement which established the first normal schools in America. Besides his writings on the education of the deaf, he published a number of essays on the philosophy of education and several text-books, including the popular *Mother's Primer* and the *Child's Picture Defining and Reading Book*. His *Plan of a Seminary for the Education of Instructors of Youth* (Boston, 1825) gave rise to the normal school idea in America. He died at Hartford the 9th of September, 1851. W. S. M.

**GALLAUDET COLLEGE, WASHINGTON, D.C.**—A coeducational institution for the higher education of the deaf, founded in 1864 as the National Deaf-Mute College. The present name was adopted at the request of the alumni in 1894 in honor of Thomas Hopkins Gallaudet (*qv*). The course given by the college extends over five years, including one year of preparatory work. A general course in the essentials of a liberal education is given leading to the degrees of BA and BS. A normal course is maintained for training hearing persons who are already graduates of colleges and wish to become teachers of the deaf. There are fourteen members on the faculty.

**GALLOWAY, SAMUEL** (1811-1872) — A pioneer of the common school movement in Ohio; was graduated at Miami University in 1833. He was teacher and principal of schools in Ohio, state superintendent of public instruction (1844-1851), and professor in Miami University. He was one of the organizers and the first president of the Ohio State Teachers' Association. W. S. M.

**GALLOWAY COLLEGE, SEARCY, ARK** — An institution for the education of women under the auspices of the Methodist Episcopal Church, South, established in 1890. Preparatory, collegiate, and music courses are offered. Twelve units are required for entrance to the college course which leads to the AB degree. There are nineteen teachers on the faculty.

**GALTON, FRANCIS** (1822-1911). — A celebrated English scientific investigator, born in Birmingham, England, in 1822, of a distinguished family. His paternal grandfather, a Quaker and a business man of ability, was interested in the study of birds and in statistics. A cousin, Sir Douglas Galton, was an eminent engineer. This mathematical inheritance was supplemented on the mother's side by genius in the study of nature. Galton's maternal grandfather was Erasmus Darwin, hardly less remarkable a naturalist than his illustrious grandson, Charles Darwin. Galton studied at Trinity College, Cambridge, and took the degree of BA in 1844. He began his career as an explorer of the upper Nile, and later of Damaraland in Southwest Africa. In the latter region he discovered the Ovampo race, an agricultural people. As an explorer he not only added materially to anthropology, etc., but also to the methods by which expeditions can most successfully be carried on. His results were published in the Royal Geographi-

cal Society's Journal for 1852, and in his books, *Narrative of an Explorer in Tropical South Africa*, and *Art of Travel or Shifts and Contrivances in Wild Countries*.

The second phase of Galton's activity concerns meteorology. He invented the graphic method of indicating weather conditions, which is to-day used in connection with weather forecasts. It appears in his *Meteorographica*, or *Methods of Mapping the Weather*, published in 1863. He also developed the theory of anti-cyclones especially valuable in such prognostications. In addition he invented many instruments useful in meteorologic observations. The phenomena of meteorology are so complicated that predictions can be made only in terms of probability and on the basis of extensive statistical data. These methods, Galton conceived, should be applied to biology, anthropology, and psychology, for here, too, the conditions are exceedingly complicated, and statistical methods and probabilities are an appropriate foundation and form of expression for predictions. His work in these fields constitutes the third phase of Galton's activity. He began with the study of heredity, and in 1869 published his *Hereditary Genius*, in which he demonstrated the inheritance of genius. A child whose ancestors are talented is shown to have a much greater chance of being well endowed than one not possessing such an heredity. He continued his studies of eminent men in his *English Men of Science*, published in 1874. Later he took up the investigation of the nature of mental powers, and to get material, devised the method of the *questionnaire*. He used this method especially in the study of mental imagery, in which his researches, published in 1883 in *Inquiries into Human Faculty*, are classic. The method of the *questionnaire* also gave him his data in regard to family faculties, by which he was enabled to make a careful quantitative study of the types and amount of inheritance. In these studies, published in 1889 in *Natural Inheritance*, he developed an ingenious method of using the probable chance distribution of variable factors as a basis for estimating the likelihood of the presence of any chance tendency disturbing such a distribution. He also laid the foundation for his *Law of Ancestral Inheritance* (see HEREDITY), which he stated in a paper presented before the Royal Society. In connection with these anthropological and psychological researches he invented composite photography, as a means of bringing out the typical facial characteristics of a group. He also discovered the unique character of the arrangement of the lines on the fingers of any individual, and his works on *Finger Prints* and an *Index of Finger Prints* formed the basis of the Bertillon system of identifying criminals. The latest work of Galton concerns eugenics (*qv*), by which he meant the science of controlling mating in the interest of the preservation and improvement

of the type This practical application of his studies in heredity has an immediate relation to education, since it is upon this agency that the principles of eugenics must in the main depend in order to reach the individual and affect practice. It is likely, however, that the greatest service rendered by Galton to education consists in the statistical methods by which quantitative accuracy can be introduced into the complicated phenomena of mental culture. Only thus can educational theory and practice be given the convincing character of science. Galton died on Jan. 17, 1911.

**GAMALIEL** — (Grandson of Hillel, and the founder and head of the liberal school which bore that name, was one of the most distinguished of Jewish scholars and educators. In such high respect was he held that at his death, according to the Mishna, "reverence for the law ceased and purity and abstinence died away," such was their sense of loss in the death of their greatest bulwark of learning and morality. Under his influence instruction in the Jewish law was more fully imbued with the spirit of practical life than in later times. He was an enthusiastic student of Greek literature, which was held in abhorrence by the rabbis and forbidden to the young. His influence appears in the training of St. Paul, who prided himself upon having sat at the feet of this greatest of Jewish teachers. His enlightenment and toleration are apparent in his verdict as President of the Sanhedrin of Jerusalem in the trial of St. Peter and other Apostles (Acts v, 33-42). The tradition that Gamaliel became a Christian and was baptized by St. Paul is inconsistent with the honors afterwards heaped upon him by the Jews. W. R.

FRANKEL, Z. *Hodegetien* (Leipzig, 1859)

**GAMES.** — A game is a form of play in which the players adhere more or less strictly to certain traditions, regulations, or rules, written or unwritten. Games are a later development of play (*q.v.*) Phylogenetically and ontogenetically informal play precedes formal play or games.

**Origin** — The origin of most existing games is obscure. Falkener has traced some to certain rites of divination, and Culin also asserts that games were derived from serious religious ceremonies. Even as late as the Olympic games of Greece and the Ludi Apollinares at Rome athletic games had a religious significance. Nearly all our existing games are modified forms of games of great antiquity. Culin says, "It is safe to say that no new game has been invented during the historic period, and that all we regard as new are only modifications of games played before the building of the Egyptian pyramids." "Among the pictures of ancient Egyptian games on the tombs of Beni Hassan" (3000-2500 B.C.), says E. B. Taylor, "one shows a player with head down so that he cannot see what the others are doing with their clenched fists above his back." This game is played by boys to-day. It is the American game sometimes called "Biff," the English game of "Hot Cockles," the French game of "Main-Chaude," and the Greek "Kollabismos." Taylor calls attention to Luke 22:64 "And they blindfolded him and asked him saying, Prophecy who is he that struck thee?" Among the games of the American Indians are found the prototypes of dice, cards, chess, golf, shinney, baseball, and racket.

Games, like informal play, doubtless grew out of experience. Among the first games of children are games of chasing, throwing, and striking. These suggest the hunting and fighting experiences of the race. A. B. Gomme in her notable study of the games of children has classified games according to the experience represented, as contest games, marriage games, funeral games, harvest games, divination games, etc. Many folk dances especially suggest experience. Among the Indians, dances represent scenes of the hunt or the war-path. Among civilized people, many folk dances represent industrial experiences, as in the harvest and weaving dances.

**Practical Uses of Games.** — The uses of games may be divided as follows:

A Fundamental	B Incidental
(1) For conservation	(1) Recreational
(2) For development	(2) Substitutional
(3) For education	(3) Prophylactic
(a) Physical	(4) Cathartic
(b) Mental	(5) Corrective
(c) Moral	(6) Vicarious
(d) Social	

**Conservation** — It is the office of games to conserve certain essential characteristics, certain fundamental interests and powers. It is a principle in evolution that when an organ develops from a lower to a higher form there is a tendency toward a loss of some excellence.

formerly possessed. In any period of rapid evolution there is always a danger that the passing of the old may be too rapid or too complete, that the foundation may be sacrificed to the superstructure, that the fundamental may be depleted in the acquisition of the accessory. It is of great importance in the evolution of a species that right proportions be maintained between that which was the old and that which is the new. This danger that is present in the development of a species is increased in the case of the recapitulatory process in the individual, a fact of tremendous importance in education.

Now James has shown that many essential hereditary characteristics are conserved by means of instincts. That is, what is really inherited in such cases is only a potentiality or tendency, and the survival of the characteristic, or power, depends upon habits formed through instinctive reaction to the environment. But many instincts ripen at a certain age, and then weaken or disappear. If a habit has been formed meantime, well and good, if not, it is likely never to be formed.

It is well understood that there is a progression of games in childhood and youth corresponding to the progression of interests and powers through the various periods of growth and development. These various games call out, exercise, and develop certain fundamental physical, mental, moral, and social traits of peculiar interest at the several periods. If no adequate opportunity be provided for the kind of play necessary to call out, exercise, and develop these traits at the time of keenest natural interest in them, these interests tend to fade away, as is the case of the instincts mentioned by James, and the most favorable opportunity for forming habits of reaction in accord with these is lost. "If," says James, "a boy grows up alone at the age of games and sports, and learns neither to play ball, nor row, nor sail, nor ride, nor skate, nor fish, nor shoot, probably he will be sedentary to the end of his days, and, though the best of opportunities be afforded him for learning these things later, it is a hundred to one but he will pass them by and shrink back from the effort of taking those necessary first steps, the prospect of which at an earlier stage would have filled him with eager delight." So, on the moral side, if a boy grows up alone and does not learn to play games which call for great activity, competition, courage, fortitude, perseverance, fairness, generosity, loyalty, cooperation, sacrifice, he loses the most favorable opportunity for the development of these traits in him. While it is possible to conceive that work might at a favorable time provide opportunity for the exercise of these traits, yet work, in so far as it departs from play, in the psychological sense, must in the nature of the case be so much be educationally less effective.

*Development* — The normal development of

an organ depends upon three factors. (1) natural impulse to growth, or heredity, (2) nutrition; (3) exercise. According to Tyler, there seem to be three stages of development. (1) A period of growth in which there is little or no exercise of the organ. (2) A period in which growth continues and modification of internal structure, under the stimulus of exercise, begins. (3) A period after growth in size and weight has been attained, in which exercise and structural change continue, as the organ approaches maturity. When we consider that the game interests have their genesis in structure which at its various stages of development calls for exercise appropriate to its needs and powers, it necessarily follows that the kind of exercise supplied by the games must in turn greatly stimulate growth and development. Moreover, the emotional accompaniment of joyous participation in games and the effect upon the vaso-motor system tend to bring about a condition of full nutrition of the developing organs. This explains the exhilaration which accompanies participation in games like baseball and tennis, for example. In short, appropriate games provide the exercise which is suited to the present needs and powers of the developing organs, the exercise which best stimulates growth and structural change, and which also stimulates the vaso-motor system and tends to bring about a condition of full nutrition.

*Education — Physical* — The value of games in physical education is obvious. Moreover, it is interesting to note that games have been the conservative and not the radical element in systems of physical training. Of the great systems of the world, the Grecian, the medieval, the British, the German system of Guts Muths and Jahn, and the Swedish system of Ling, the exercises of the first three were largely or wholly games, there was a large element of games in the fourth, and there is especially in America a constantly increasing element of games in the last. It is now very generally recognized that specific movements designed for the development of particular muscles or groups of muscles and performed while consciousness is largely absorbed in the execution of the movements, are not, from the standpoint of health and vitality, as beneficial as the exercises involved in games, in which there is a far larger element of pleasure and little or no consciousness of the details of the movements executed.

*Mental* — Recent studies of the relation of motor ability to intelligence have emphasized the educational value of play activities. Mosso and others have shown that the phenomena of muscular fatigue and mental fatigue are identical. Fatigue of the muscles is attended by a loss of power of attention, and fatigue of attention by loss of power of the muscles.

Educationally, games develop power rather than extend intelligence, that is, develop an

ability to apply what one knows rather than give comprehensive knowledge which may or may not be applied. Educationally games excel in this, that they develop a capacity for instantaneous and perfectly coordinated reaction to situations within the field in which the education applies, however restricted that field may seem to be. In emergencies, crises, in time of stress, excitement, or peril, within the field of action analogous to that covered by games, games provide a training *par excellence*. For example, games may furnish no definite knowledge that would enable a lawyer to conduct a case successfully, but they do provide a training which would enable a lawyer, under the strain of an exciting trial, in full possession of himself, to concentrate and coordinate every power to the task in hand.

**Moral** — The relation of games to moral training has always been recognized to a certain extent. However, a far greater appreciation of the moral significance of games has come about in recent years, through the stimulus of a new appreciation of the meaning and significance of play in general, and notably by such a study as Guheik's *Psychological, Pedagogical and Religious Aspects of Group Games*. The generally accepted theory that evolutionary progress has been from the fundamental to the accessory and that this same order, in a general way, is observed in the normal development of an individual, has as apt an application in the field of conduct as in physical or intellectual development. One readily recognizes that there are certain fundamental virtues which are the basis of later accessory moral qualities. Now, the significance of games in moral training lies not alone in the opportunity for the exercise of fairness, courage, cooperation, etc., but especially in the fact that children and youth have, at a certain age, an instinctive interest in just these fundamental virtues. Just as the developing organs call for physical exercise of a type appropriate to their needs and powers, so also the moral nature or organism calls for a display of certain types of character appropriate to the stage of development. For example, the individual competitive games of boys from ten to twelve call for such traits as courage, hardihood, pugnacity, fairness. The boy who displays these qualities is admired by his companions, and the boy who lacks them is not. But physical courage is a prototype of moral courage, hardihood of fortitude, pugnacity of righteous wrath, fairness of justice.

**Social** — A game is socialized play. Games necessitate an appreciation of social relationships, and there were no games until the race had developed a capacity for social activities. Since games developed commensurately with the capacity of the race for social activity, there is in games a review of the social development of mankind.

There are several obvious applications of the social influence of games, as for example —

1 In the development of sociability and sympathy.

2 In the training and control of the fighting instinct, or the instinct of competition, as a basis of noble emulation on the one hand and of capacity for righteous conquest on the other.

3 In the training for cooperative action.

4 In providing an outlet for types of activity that might otherwise become anti-social.

Games might be classified according to social significance, in three classes —

1 Sociable or cooperative games, such as the dramatic and imitative games of children, folk games, dances, group singing.

2 Competitive games, such as wrestling, boxing, racing.

3 Cooperative-competitive games, such as baseball, football, basketball.

The emphasis of interest in these games is somewhat as follows. In sociable or cooperative games, to about seven (possibly, in the case of girls, at all periods), in competitive games from about seven to about twelve, in cooperative-competitive games, from about twelve on.

**Incidental uses of games** — *Recreational*

— Since games have the uses mentioned under Conservation, Development, and Education, they are, for children and youth at least, to be regarded as having a far deeper significance than the merely recreational, yet the recreational effect of games as a change from study and sedentary pursuits and its value are obvious.

**Substitutional** — Games provide a useful substitute for what might prove harmful activities. They also divert from undesirable states of consciousness, as in disappointment, anger, morbid introspection and the like. "Horse play," orgies, outbreaks, might often be diverted through the legitimate channel of games.

**Prophylactic** — Games often prevent anti-social activities and the acquisition of anti-social habits. Boys are arrested for misdemeanors in throwing, stoning windows, snowballing pedestrians, provoking persons, even policemen, to chase them, etc. Ball games and running games provide the same activity and excitement in a legitimate form.

**Cathartic** — Aristotle thought that certain primitive instincts could be purged away by harmless means, as by the drama, and in this way harmful and anti-social expression of the impulse be prevented. Strictly, games should not be regarded as cathartic so much as directive. Games serve not so much by purging away as by training and directing the primitive instincts. For example, boxing under right conditions diminishes fighting, not, however, by purging away the fighting instinct, but by directing and controlling it, making it a basis for a higher expression in games and in

# SUMMARY OF ACTIVE PLAYS AND GAMES MOST BENEFICIAL AT DIFFERENT AGES

17-20	Achievement of puberty and in general of growth and height Greater growth in breadth	Continued development of association fibers	Highest achievement in exercises of quickness Growing capability to perform exercises of strength and duration	High ideals of sportsmanship Fortitude Magnanimity Justice								

Sober Period

Competitive Period

Coöperative-competitive Period

## GAMES

the affairs of life All social, moral, and civil leaders, reformers, and martyrs have possessed in a high degree this primitive instinct trained to a higher and nobler expression

**Corrective.** — Games supply exercises best adapted to develop in a normal child perfect physical form and proportion This is obviously so inasmuch as they involve the types of activity which shaped the body in the process of evolution. When the body of a child has become ill-formed through some cause or other, games, wisely chosen, may supply a most valuable corrective

**Vicarious.** — The value of a game is not alone to the players. Games benefit those who only stand and wait The sympathetic participation of little children in the game they are watching is evident to the observer.

Heightened color, deepened breathing, accelerated heartbeat, joyous emotion, muscular movements, are all present. The recreational value of professional baseball to the spectators is due not alone to a shifting of attention from ordinary channels to the game but also to a genuine participation, to a degree, in all the emotions and movements of the players themselves

**Practical Application** — Games serve a fundamental need in education, physically, mentally, morally, and socially and should be regarded as essential to a school curriculum. For that portion of a community not in educational institutions, adequate play facilities are as truly necessary for social order and civic progress as our lecture halls, reading rooms, libraries, and museums.

## GANGLION

**Time to be given to Plays and Games.** — The following diagram suggests the amount of time that might profitably be given to plays and games at different ages.

**Selection of Games** — Games should be selected to meet the peculiar needs and opportunities of the successive periods of development. Physically, they should further the best physiological growth at the period of their most rapid development. Mentally, they should provide expression for the nascent interests and emotions of the period. Morally, they should stimulate conduct in accord with the elemental virtues and ideals toward which there is an instinctive response. Socially, they should involve an expression of the social interests and the form of social organization adapted to the stage of development

The following chart may prove suggestive in relation to the choice of games G E J

For philosophical theory of games, see PLAY

**GARDENS, SCHOOL; GARDENS FOR CHILDREN**

— Most gardens which are definitely planned with reference to the education of groups of children are under the management of schools, and hence are usually known as school gardens. In America and England many excellent gardens are conducted for similar educational ends, but quite independently of schools. Hence the term school garden has come to be applied rather loosely to any children's garden designed for educational purposes, especially for teaching about plants and methods of gardening by the active or laboratory method. This latter qualification distinguishes school gardens from botanical gardens, which are usually of educational value to children in that they exhibit plants merely for observation.

As to the definite educational aims of school gardens, the great majority of those in continental Europe were originally intended for teaching practical gardening and agriculture as a phase of vocational education; and there is developing a similar tendency in some villages and rural districts of America and England. But the great majority of school gardens in America and England and many in various countries of the continent of Europe are now being conducted as a phase of nature study with a general cultural rather than vocational aim. Probably nine out of ten of the children who have worked in American school gardens in the past ten years lived in towns and cities and had little prospect of ever engaging in the business of raising plants for market; so that the gardens have obviously not developed in response to stimulation by the growing agricultural phase of vocational education, but are now conducted simply as a very practical part of the larger nature study or general science movement which aims to present the scientific study of common natural objects and processes from the point of view of general elementary education. Only a relatively limited number of gardens in rural districts in America have been definitely modified to meet the demands of agricultural education, and this chiefly for specially selected pupils of high school age.

In many cities in the United States, notably at Cleveland, O., children's gardens have been made at the homes of individual pupils, but under the guidance of a teacher who gives general directions at school, and occasionally makes a tour of inspection. On the whole, the results from home gardens have been far more satisfactory than from school gardens, probably because of the great personal interest which children take in home gardens, and because the gardens have a definite influence in stimulating the desire to beautify home surroundings. School gardens are, however, needed for giving practical lessons before the pupils attempt to make gardens at home; and it seems to be the consensus of opinion that schools should maintain gardens of limited size

for teaching purposes while encouraging the development of home gardening as far as possible.

Two general plans have been tried in school gardens: the individual-ownership system, and the community system. Under the first plan the garden is divided into plots which become the property of the individual pupils for a season, and the owners have absolute control of the produce. Under the community system the produce of the garden is either used for lessons in the school or is sold and the proceeds devoted to the school library, a hospital, sick children, or some other altruistic purpose. The first plan is the easier to administer; the second gives greater results. The two plans have been combined in some gardens, for example, by growing vegetables in plots controlled by individuals, and flowers in community plots, in the working of which all pupils cooperate.

Comenius, Rousseau, Pestalozzi, and Froebel recommended the development of children's gardens for educational purposes. In the first half of the nineteenth century the educational authorities of several German states introduced gardening into rural schools, and the movement later extended to many city schools. Berlin has large grounds outside the city limits, and any child may have space for a small garden. Several German cities do not place emphasis upon work by the pupils, but have botanical gardens for instruction by observation and for supplying nature-study materials to the schools. In short, the German city schools maintain gardens for general educational rather than for vocational purposes. Following the example of German gardens, Sweden, Austria, Belgium, Holland, France, Switzerland, and Russia have given official encouragement to school gardens within the past fifty years. In these countries the rural schools have been encouraged to establish gardens, and in the beginning the aim seems to have been entirely vocational. The total number of gardens connected with schools on the continent of Europe is now over 100,000. Switzerland requires special training in gardening in the normal schools, and since 1885 has subsidized elementary-school gardens. For more than thirty years every rural school in Belgium has had a garden, and the training in gardening is believed to have been invaluable in relation to the chief industry of the country. The normal schools of France teach agriculture and gardening, and it is estimated that over 40,000 schools have gardens. It is an open question, however, whether a large proportion of these have been of much value to the pupils. Russia has encouraged gardening for more than twenty years, and many schools assign small gardens to individual pupils. The normal schools teach gardening, and special courses have been given to teachers. In Holland the small children have gardens, apparently intended for nature study, rather than for train-

# SCHOOL GARDENS.

ing in the business of gardening. Italy has within recent years shown interest in school gardens. Ten years ago there were less than a hundred gardens in Great Britain, and these not officially connected with the school system. Since 1904 gardening has been encouraged by special grants to the schools. Many gardens have been established in connection with elementary day schools, and also in evening schools for pupils who must work during the day. In the day schools the nature study aims seem to prevail, but the gardens are expected to have a vocational influence. England has been often criticized for slow development of school gardens, but it should be noted that a widespread popular interest in home gardening has probably been a good substitute for hundreds of the inefficient school gardens established officially on the continent of Europe.

In Canada interest in school gardens has developed rapidly in the past ten years. In 1905 there were more than a hundred gardens in Nova Scotia under the direction of the superintendent of education for the province. In each of the other eastern provinces five gardens were established in connection with the MacDonald schools in 1904. Many other gardens are now an established part of the school work, and the schools receive special grants from the education departments. There are many school gardens in the Northwest Territories.

Most of the gardens in the United States have been organized during the past ten years. Among the pioneer gardens which attracted general attention were the wild flower garden at Roxbury, Mass., in 1891; the gardens of the National Cash Register Company, at Dayton, Ohio, 1897; at the Hyannis (Mass.) Normal School, 1897; the home gardens at Cleveland, Ohio, 1900; the Hartford (Conn.) School of Horticulture, 1900; at Hampton Institute (Va.), and the Children's School Farm in New York City, 1902. Most cities have school gardens, but they are usually fostered by individuals or organizations independently of official connection with the schools. As examples of such outside encouragement of gardens the following have been prominent: Home Gardening Association of Cleveland, Massachusetts Horticultural Society, Twentieth Century Club of Boston, Woman's Institute of Yonkers, Massachusetts Civic League, Missouri Botanical Garden, National Cash Register Company, Vacant Lot Cultivation Association, United States Department of Agriculture, numerous local agricultural societies, and the Park Department of New York City. In only a few cities have boards of education helped financially. The Philadelphia school system maintains some gardens, but private individuals and organizations outside the system have been active with smaller gardens in that city. Cleveland, Rochester, and a few other cities officially provide funds for gardens as part of the work of schools. Many other cities and towns recog-

nize gardening as part of the course in nature study, but do not provide for the material basis for conducting the gardens needed to carry out the school program. The vast majority of the school gardens in the United States are still officially independent of schools and conducted on the personal responsibility of teachers, principals, and others who are interested in the school garden movement. As an example of good results in spite of lack of official encouragement, New York City has over eighty school gardens, many on school grounds, but conducted by enthusiastic members of the New York School Gardening Association without appropriations from school funds. In fact, most school gardens in the United States outside the largest cities need little financial help from the school authorities, for in most places land is available, the pupils do the work, the seeds cost little and the produce will pay for them, and an energetic director can usually find ways and means for collecting the necessary tools. There is probably an advantage in that gardens without the financial support of schools tend to develop the resourcefulness of the individual pupils and to awaken the interests of their parents and friends. Instruction in methods of gardening offers no special difficulties now that gardening is commonly recognized as a very important phase of nature study and science, and hence properly comes under the direction of teachers of those subjects. The common result is that the garden work is used and correlated in the classrooms much more than would be possible by special garden teachers. The fact is that throughout the United States there is little demand for special appropriations for school gardens, except for modest equipment for tools. Much more important is the official recognition of gardening as a phase of nature study and therefore a legitimate part of the regular work of teachers assigned to the classes in that subject.

The care of school gardens during the long summer vacation is a difficult problem which has retarded the general success of the movement. A hired gardener is undesirable, for in his work the pupils have little interest. School gardens will be most useful if conducted by the pupils and for the pupils of the school. The most satisfactory plan, judged by educational results and pupils' interest, is the committee system. This means that the director of the garden appoints groups of pupils as committees charged with the care of the entire garden for set periods during the vacation, and required to report to the school in September. Some voluntary supervision by interested adult citizens is usually possible, especially where there is some local society which is interested in the garden movement.

With regard to the general educational influence of school gardens, it has been claimed by numerous teachers that many pupils make

more rapid progress in their book studies after being aroused by the garden work. Such increased efficiency has been found to have an indirect moral influence, and in many cities the boys engaged in gardening seem to have lost their former interest in mischief making, perhaps because their time has been occupied with the interesting work of the gardens. Probably a large part of the advantages claimed for manual training as a phase of education applies to school garden work, and there is the additional gain from the garden in that the work is in the open air and combined with nature study. Under such conditions the garden may become a most important agency for healthy recreation, for developing an interest in nature, and for giving the pupil direct contact with a phase of industrial education, which may be of vocational value to some, but of far greater importance to the many, in that it gives them a sense of personal relationship with that vast part of the world's work which is centered around the cultivation of plants for human use. This tendency of gardens to develop a personal interest in plant growing outside of the plot controlled by the pupil is so marked that several societies concerned with the beautifying of cities by encouraging the cultivation of plants in both private and public grounds, wherever possible, have officially recognized school gardens as very important factors in developing personal responsibility for better civic conditions. No doubt a garden can be made very helpful in this direction, but the result will come from the teaching and not from mere digging in the soil. In fact, the value of merely working in the garden has been overestimated, and the future efficiency of gardens as part of general education will depend upon lessons which are drawn from materials and conditions available in well-managed school gardens. The purpose of school-gardens is not simply to raise plants, but rather to use the methods of gardening and the growing of plants as a concrete basis for one phase of education. Judged by this standard, a large number of gardens for children are not yet real school gardens or educational gardens, for efficient instruction is not given the pupils. M. A. B.

College, Randolph-Macon College, the University of Alabama, and the University of Mississippi, and president of Randolph-Macon College and Vanderbilt University. Author of textbooks on mathematics. W. S. M.

**GAUDEAMUS IGITUR** — Probably the best known as well as the most frequently sung of student songs in the world. The origin of this famous poem was long in doubt, but painstaking German research has established the fact that in its present form it does not go back much beyond the middle of the eighteenth century. Those who, guided solely by the content of the song, would refer it back to the whimsical laments over the vanity of human wishes and the advice to "eat, drink, and be merry, for to-morrow we die" found in the songs of the Goliards (*q.v.*; see also the article on *CARMINA BURANA*), may find some satisfaction in the fact that the basic element in the *Gaudeamus* has been traced back to a song found in a French Ms of 1267. This is a penitential psalm, in which the following lines occur:—

Vita brevis, brevitatis in brevi finietur;  
 Mors venit velociter et neminem veretur.  
 Ubi sunt qui ante nos in hoc mundo fuerunt?  
 Venies ad tumulos, si eos vis videre,

which will be recognized as parts of the modern *Gaudeamus*. But there seems to have been a number of songs which opened, at any rate, with the word *Gaudeamus*. On this account probably the well-known verses have been referred to a greater antiquity than they deserve.

Sebastian Brandt in the *Ship of Fools* (ch. 108) refers to the *Gaudeamus*, and a woodcut in the edition of 1494 represents the ship of fools and the words *Gaudeamus Omnes* issuing from the mouth of one of the passengers, written in a notation which does not call up the modern tune. Hans Sachs, in a poem written in 1568, also refers to a *Gaudeamus*. But none of these continues with the vigorous and meaningful *igitur*.

The earliest known Latin version (there is a version in German by J. C. Gunther, written in 1717, beginning *Bruder lasst uns lustig sein*) of the modern *Gaudeamus* is found in a (Ms.) copy of student songs in the Royal Library at Berlin, which was written before 1750. The version is as follows.—

Gaudeamus igitur  
Juvenes dum sumus,  
Post molestant senectutem  
Nos habebit tumulus.  
Ubi sunt qui ante nos  
In mundo vixere?  
Ab eas ad tumulos,  
Si vis hos videre  
Vita nostra brevis est,  
Brevi finietur.  
Venit mors velociter,  
Neminem veretur.

On the basis of this the other versions arose, each body of students adding something new or topical, or eliminating something. A Latin and German version is found in a Jena Ms. of 1776, showing that there was reason in the order issued at Halle by the university authorities, forbidding the singing of the song on account of its degrading vulgarity. The verses were rescued from the mire, however, in 1781, by C. W. Kindleben, at one time pastor, university docent, and assistant teacher under Bascdow at the Philanthropinum at Dessau. Kindleben's reputation was not of the best; he lost every position he held through his dissolute ways. But it was this man who cleansed the *Gaudeamus* of its obscenities and published it with a translation in its present form in *Studentenlieder Aus den hinterlassenen Papieren eines unglücklichen Philosophen, Florido genannt, gesammelt und verbessert von C. W. K.* 1781. After the student revival which took place about 1813, the song found its way rapidly into all the student song books and Commers-books, until it became the property of students in universities and schools the world over.

**GAUSS, KARL FRIEDRICH** — One of the foremost mathematicians and astronomers of the nineteenth century. He was born on Apr. 30, 1777, at Brunswick, Germany, and died on Feb. 23, 1855, at Gottingen. He was edu-

cated at Gottingen, and in 1807 he became professor of mathematics and director of the observatory in that university. To him more than to any other one person is due the prominence that Gottingen attained in the nineteenth century as the mathematical center of Germany. There was no field of mathematical activity in which he was not interested, and in most of those that were open in his time he was a successful worker. The number of his contributions was very great, notably in the theory of numbers, theory of electricity and magnetism, the interpretation of complex numbers, and mathematical astronomy. D. E. S.

**GAZA, THEODORE** (1400–1475) — Greek scholar and teacher of the Renaissance period, who came to Italy about 1440. Introduced to Vittorino da Feltrc (qv) by Ficelfo (qv), he studied Latin under him and taught Greek and copied Mss. in his school at Mantua. In 1444 he became the first public professor of Greek at Ferrara, and lectured on Demosthenes. In 1457 he was summoned by Nicholas V to Rome, where he taught Greek and assisted in translating some of the Greek classics. In 1455 he translated books for King Alfonso of Naples; he later returned to Rome, which he again left before his death, which occurred in a monastery in Lucania. Gaza wrote a Greek Grammar (*γραμματικὴ εἰσαγωγή*), which Erasmus used at Cambridge and translated into Latin and Budæus used at Paris. Copies of the *Iliad* written by Gaza are still extant one in Florence and the other in Venice. In the controversy on the superiority of Plato and Aristotle, Gaza strongly defended the latter, several of whose works he translated.

**GELASIUS** — Bishop of Rome (492–496), and author of the *Decretum Gelasii de libris recipiendis et non recipiendis*. The importance of Pope Gelasius in the history of education is due entirely to his famous decree on the canonical books of the Bible and the authoritative and approved writings of the Fathers of the Church. The decree differs from later indexes of books in that it not only gave a list of books which were condemned, but also a list of books which were approved as standards of orthodoxy. The decree was issued at a Roman synod held by Gelasius, but in its present form it contains material much earlier and has been subjected to various interpolations. The final section, however, which gives the list of books to be received or rejected, was, with the exception of manifest interpolations, the work of Gelasius. By passing judgment upon earlier writers determining which should be regarded as setting the norm for orthodoxy, the decree

undoubtedly affected profoundly the course of studies in the Church. Among other effects of the decree was the elimination of the older Alexandrine influence, *e g* that of Clement of Alexandria (*q v*). It did not become generally known in the Church till some time after Gelasius, it was not until two hundred years after its publication that it is quoted, and not until 860 that it was connected with the name of Gelasius. From that time on its influence was constantly felt. J. C. A. Jr

**GEMMA FRISIUS (1508-1555)** — The family name of Gemma the Frisian was Rainer or Regnier. He was born at Dockum, in East Friesland, on Dec 8, 1508, and died at Louvain on May 25, 1555. He was a physician, holding the chair of professor of medicine at Louvain, but he is better known as one of the leading textbook writers of his century in France on arithmetic and astronomy. His most famous textbook is the *Methodus arithmetice practice* (Antwerp, 1540), of which there were at least fifty-nine editions before 1601. He also wrote upon astronomy, and first suggested the idea of finding longitude by the help of a chronometer in his *De principis astronomie* (Paris, 1547). His influence upon arithmetic was more marked than that of any other Latin writer of his century. His son, Cornelis (1535-1577), was professor of medicine and astronomy at Louvain, and wrote on astronomy and philosophy. D. E. S.

**GENERAL EDUCATION BOARD** — An organization chartered by Congress in 1903 and originating with Mr John D. Rockefeller's Committee on Benevolence. The plan of such an organization was designed and adapted to assist Mr Rockefeller in distributing his gifts to education, but it was also intended to meet a wider need and to afford a medium through which other men of means, who desired to promote education in the United States, could do so in a systematic, intelligent, and effective way. The gentlemen forming the first Board were the late William H Baldwin, Jr, Wallace Buttrick, the late Hon J L M Curry, Frederick T Gates, Daniel C Gilman, Morris K Jesup, Robert C Ogden, Walter H Page, George Foster Peabody, John D Rockefeller, Jr, and Albert Shaw. The gifts of Mr Rockefeller to the Board and placed under its absolute control amount to \$32,000,000. Others have contributed smaller amounts, among them a gift of \$200,000 for rural negro education by the late Miss Anna T Jeanes.

The work of the General Education Board now falls into four main divisions: —

1. *The promotion of practical farming in the*

*Southern States* — Through the United States Department of Agriculture, under an agreement begun in the year 1906, the Board has made contributions for this work aggregating \$405,700. The method employed is that of demonstration farms. There are now (1911) 196 men at work supervising demonstration farms, and 19,579 farmers are pursuing agricultural methods under such direction. One hundred and fifty-four thousand farmers are pursuing similar work, influenced by those farmers who are under the immediate supervision of the agents. Nine thousand eight hundred and fifty-nine boys, from twelve years of age and up, under the general designation of Boys' Corn Clubs, are performing practical agricultural demonstration on their fathers' farms, and are making their experiments the basis of agricultural study in the schools.

2. *The promotion of public high schools in the Southern States* — The General Education Board appropriates to each state university or to the state department of education a sum sufficient to pay the salary and traveling expenses of a special high school representative, who arouses and organizes public sentiment favorable to public high schools, and who secures the establishment and maintenance of public high schools. Since the beginning of this cooperation on the part of the General Education Board with state universities and state departments of education, 703 new public high schools have been established, \$6,390,780 have been raised by the people of the several states for buildings and equipment, and the annual sum available for the support of public high schools has been increased by \$1,332,667.

3. *The Promotion of Institutions of Higher Learning* — The General Education Board uniformly makes its gifts for endowment. Appropriations by the Board for higher education have been made as follows: In the Southern States, \$2,309,000; in the Western States, \$2,510,000, in the Eastern and Middle States, \$1,805,000. Total, \$6,624,000. These gifts on the part of the General Education Board make up an approximate total of \$25,406,000, a sum which represents the increase of educational endowment and equipment of the eighty-two colleges and universities in the United States to which gifts from the Board have been made to date (1911).

4. *Negro Education* — The Board has contributed \$473,239.76 to schools for negroes. In this connection it should be said that negro farmers have shared fully in the cooperative demonstration work described above. It is the policy of the General Education Board to work through existing institutions and agencies and not itself to undertake independent educational work. E. C. S.

AYRES, L P. *Seven Great Foundations*. (New York, 1911)

**GENERAL METHOD.** — Methods of teaching which are fundamental to all the school branches, and therefore in general use, are included under the term "general method." The term is used in contradistinction to "special method," which is applied to a method used only in a single subject. Sometimes "principles of teaching" is used synonymously with "general method," the former implying a treatment in terms of theoretic generalizations or laws, and the latter one in types of practical procedure.

H. S.

See METHOD, TEACHING; SPECIAL METHODS; TEACHING, TYPES OF; TEACHING, PRINCIPLES OF

**GENERAL TERM.** — SEE CONCEPT

### GENERAL THEOLOGICAL SEMINARY

— Established by the General Convention of the Protestant Episcopal Church in the United States in 1817 and incorporated in 1822. Instruction began in New York in 1819. It was removed to New Haven, Connecticut, in 1820, but returned to New York in 1822. It is the only seminary in the Episcopal Church under the control of the General Convention. The buildings include a large chapel, lecture hall, nine dormitories, library, gymnasium, refectory, and nine residences for dean and professors. The halls can accommodate 150 students. In 1911 there were 143 students, fifteen professors and instructors, and one lecturer. It confers no degree on graduation. The degree of Bachelor in Divinity is conferred for graduate work only. The degree of Doctor in Divinity is conferred for work required or *honoris causa*. There are about 1800 graduates, of whom nearly 1000 are living, and about 1000 former students who are not Alumni. C. B. Z.

See THEOLOGICAL EDUCATION

**GENERALIZATION** — The process by which a principle or law is reached, the term is also used to denote the product. The term expresses the use or function of induction, which endeavors, beginning with a number of scattered details, to arrive at a general statement. Generalization expresses the natural goal of instruction in any topic, for it works a measure of economy and efficiency from the standpoints alike of observation, memory, and thought. The number of particulars that can be obtained is limited. When, however, different cases are brought together, — and this bringing together is expressed in a general principle, — a great variety of cases are practically reduced to one case, and further observation is freed to attack new particular things and qualities not yet systematized. Exactly the same holds good for memory. There are a few prodigies who can carry in mind an indefinite number of unrelated details; but most persons need the help of generalizations in order to retain special facts and to recall them when needed. Logically, a prin-

ciple not only sums up and registers the net intellectual outcome of a great many different experiences which have been undergone at diverse times and places, but is an illuminating and clarifying means of interpreting new cases that without it could not be understood.

Because the older deductive, classificatory schemes of instruction began with a statement of the law or principle, educational reformers who were influenced by the scientific movement toward induction were compelled to emphasize the later and derived place occupied by generalization in the intellectual life. Zealots for the new method sometimes swung to the extreme of reaction against universals, and, treating observation and imagination of particulars as an end in itself, neglected the importance of generalization as a normal terminus of study. Another educational error is to suppose that generalization is a single and separate act coming by itself, *after* the mind has been exclusively preoccupied with particular facts and events. To the contrary, generalization is a continuous, gradual movement away from mere isolated particulars toward a connecting principle. A necessary part of the work of instruction is, therefore, to make the conditions such that the mind will move in the direction of a fruitful generalization as soon as it begins to deal with and to collect particulars. The resulting generalization will, of course, be crude, vague, and inadequate, but, if formed under proper conditions, it will serve at once to direct and vitalize further observations and recollections, and will be built out and tested in the application to new particulars. This suggests the final educational principle. A generalization or law is such not in virtue of its structure or bare content, but because of its use or function. We do not first have a principle and then apply it; an idea becomes general (or a principle) in process of fruitful application to the interpretation, comprehension, and prevision of the particular facts of experience. J. D.

See ABSTRACT AND CONCRETE, CONCEPT, EMPIRICAL.

**GENERALIZED HABITS** — See HABIT; also FORMAL DISCIPLINE; ABILITY, GENERAL AND SPECIAL

**GENERIC IMAGE** — When one sees a single object and remembers it, he carries away a more or less complete reproduction of the experience which he derives through contact with this object. The remembered experience is in the form of an image. After contact with a number of different objects closely related to each other in character, memory reflects certain elements and drops others. Those characteristics which are common to all of the specimens stand out with increasing vividness, those characteristics which belong to single individuals tend to be obliterated. There arises in this fashion

a generic image Sir Francis Galton used the figure of a composite photograph in describing these generic mental images The analogy is undoubtedly justified in certain cases, although it is probable that very few such images are used by the ordinary observer in his common experience

C. H. J.

GALTON, F. *Inquiries into Human Faculties*. (Appendix) (New York, 1883)

**GENETIC METHOD** — Mental processes can be studied by a variety of different methods Thus, they may be analyzed or they may be studied with reference to their relation to the general life processes of the individual, or, finally, they may be studied with reference to their development and the development of the individual who possesses them The relative level of evolution reached by the individual may also be studied Whenever the problem of development or evolution is foremost the method of treatment is said to be the genetic method Thus one may study the growth of a tendency on the part of children to use abstract ideas The growth of this tendency is a genetic process, and the study of the habit constitutes a genetic problem Again, one may study the presence of ideas in animals There has been recently an increasing tendency to recognize the fact that psychology can be productively applied to education only through the working out of genetic methods In some cases the term "genetic" has been used in a limited sense to apply to the special problems of child study; but this restriction of the term is misleading, and any form of study of mental development or mental evolution should be included under the term "genetic"

**GENETIC PSYCHOLOGY.**— See PSYCHOLOGY, GENETIC.

**GENEVA.**— See CALVINISTS AND EDUCATION; SWITZERLAND, EDUCATION IN.

**GENEVA COLLEGE, BEAVER FALLS, PA** — A coeducational institution which was opened in 1849 by the Reformed Presbyterian Church of North America at Northfield, Ohio, and moved to its present location in 1880. Preparatory, collegiate, music, and fine arts departments are maintained The entrance requirements are equivalent to about fourteen points of high school work The degrees of Bachelor of Arts and Bachelor of Science are conferred on those who complete the require-

ments, which include residence for at least three fourths of the college course at an accredited college with the senior year at Geneva. There is a faculty of twenty-three members.

**GENEVA, SWITZERLAND, UNIVERSITY OF.** — Established in 1573, being the outgrowth of the Academy founded by the Republic of Geneva in the year 1559 The theological faculty of the old Academy attained a period of considerable renown under men like Calvin and Beza During the stormy days of the seventeenth century the institution entered upon a decline, but was given a new lease of life as a result of the persecutions of the Huguenots in France, the Academy gradually having become the acknowledged center for the dissemination of Protestant culture in French-speaking territory. From 1798 to 1814 the Academy was in French hands

The present university comprises the faculties of Protestant theology, law, medicine (1876), letters and social science, and pure science, the language of instruction being French Affiliated with the institution are a natural history museum, a botanical garden, and an observatory The library contains over 170,000 volumes and about 1800 manuscripts The University of Geneva is the second largest institution of higher learning in the Swiss Confederation, being exceeded in the number of students only by Berne During the winter semester of 1909-1910 there were enrolled 1915 students, of whom about half were women Of the matriculated students only 23 were registered in the theological faculty, while the medical school attracts the largest number of students, viz., 624, including 372 women As at all of the Swiss universities, the number of non-matriculated students is relatively large, 136 men and 327 women

**GENIUS** — A term used somewhat loosely to indicate the highest type of human ability Below genius comes the grade of talent, and below talent ordinary ability It is evident, however, that these grades are not enough to indicate very definitely the rank of any individual Galton in his study of hereditary genius distinguishes eight classes above that of ordinary talent Cattell endeavors to determine by a statistical study of biographical dictionaries the thousand most eminent men in history These he ranges in regular order on the basis of the amount of attention to which each was deemed worthy by the various editors. Thus each individual is given a specific place instead of being assigned to a group He concludes that the ten most eminent men are Shakespeare, Mahommed, Napoleon, Voltaire, Bacon, Aristotle, Goethe, Cæsar, Luther, and Plato

Genius is more commonly treated according to the special sort of ability involved, since men may show the highest power in certain fields and be commonplace or even defective in other respects. The leading types seem to be the artistic, the intellectual, and the practical. The artistic type includes literary genius, the intellectual embraces philosophic and scientific power, while the practical covers such fields as statesmanship, business ability, and generalship. It is possible that outside these powers there lies another group, the moral and religious. However, in so far as these gifts involve intellectual qualities, they are allied to the philosophic and artistic types. On the other hand, they are usually associated with intensity of sympathy, a power of self-sacrificing service, and a firmness of adherence to ideals that constitute of them a somewhat distinct kind.

The genius may, from a biological point of view, be regarded as a variant from type. It must be noted, however, that his variation is in the direction of extraordinary new efficiencies. Much has been made by Lombroso and others of the idea that genius is allied with, if not a form of, insanity. It is true that many men of genius have shown signs of insanity. It would seem likely that the marked ascendency of certain powers in genius would involve a lack of balance which might amount or lead to insanity. Especially in the artistic type do we find such abnormalities. Nevertheless, even the artistic genius must show an excellence of judgment in reference to his art which suggests a "method in his madness." In general, the genius owes his success in the field of his pre-eminence to the sanity which he displays therein, although his emotional intensity, his nervous sensitivity, his vigor of imagination, or his power of concentration may lead him into eccentricities or undermine his judgment.

The interpretation of the genius as a degenerate is closely associated with the view that he is insane. The loosening of inhibitions, the emotionalism, and the general neuropathic condition found in degenerates may lead, especially in art and religion, to results that seem to have a touch of genius. At least, they attract attention, and often help the one who employs them to get a following. On the other hand, it is quite certain that, in general, the genius displays variations that are in advance of his type. He is the *superman* rather than the *degenerate*. Like the insane or the eccentric, he defies rule and precedent, yet in the interest of greater rather than less efficiency. His originality is not mere variation, but meets the requirements of judgment.

The studies of Galton and Wood show clearly that genius is inherited. Since, however, it is rare that both parents possess extraordinary power, the children of geniuses show, as a rule, a marked tendency to regress toward mediocrity. The absence of any form of selection that favors the survival of the very talented as

against the common run of men makes it unlikely that this tendency toward regression shall be interfered with. The genius can, therefore, hardly be taken as a prophecy of the type toward which the race is tending.

On the question of the dependence of the genius on his environment we have the common notion that opportunity is essential to greatness, opposed to the view, championed by Carlyle, that genius always creates its opportunities. While it is doubtless true that extraordinary gifts do not insure their possessor his proper rating, still the abilities of men of genius are usually sufficiently broad in scope to enable them to attain distinction along some of the lines of opportunity open to them. There are probably very few "unappreciated" geniuses, and most of those who rate themselves as such are, doubtless, because of their lack of some qualities essential to efficiency, properly characterized as "cranks."

Genius is frequently, if not usually, foreshadowed by precocity. This is especially true of artistic genius. Many of the greatest musicians have, like Mozart, been "infant prodigies." Literary power is the latest among the artistic gifts to display itself, but even here talent may be shown in childhood, as witness Goethe, Victor Hugo, Shelley, and Keats. Sometimes scientific and philosophic or administrative power is evinced in early youth. Newton, Berkeley, Herbart, William the Conqueror, and Alexander the Great are illustrations.

It has been thought that genius does its best work in the earlier years of life. The celebrated statement of Dr. Osler was to the effect that, although many great achievements were accomplished after the age of forty, still, the world would be where it is, if all great men had died at that age. Dr. Dorland's careful study of the history of eminent men shows, however, that the greater part of their extraordinary work was done after this age, and indeed, not a little after the age of sixty.

So far as education is concerned, the problem of training the genius does not differ from that of training any of more than average ability. The tendency toward uniformity in our schools may prove unfortunate for the unusual mind in two ways. It may keep him wasting time with the crowd, when his abilities would, if properly developed, put him far ahead. It may lay so much stress on studies in which he is not capable as seriously to retard the development of his special power. The school reformers are actively endeavoring to break up this mechanical uniformity of studies and of progress through the grades. Many devices are being developed for getting at the individual, for helping him to find his special bent, and for putting him in a position to progress as fast as his talents and energy will permit. All these will assist in the education of the genius, and although he may be less dependent upon environment than are those of inferior ability,

nevertheless, he needs and profits by the proper education. It remains one of the leading problems of the school to discover and properly train the exceptional man. E N H

**GENLIS, STÉPHANIE FÉLICITÉ DU CREST DE SAINT-AUBIN, COMTESSE DE**—commonly known as **MME DE GENLIS** (1746–1830)—One of the leading French women educators of her day. According to Sainte-Beuve, “She was a woman teacher, she was born with the sign on her forehead.” She was governess in the family of the Duchesse de Chartres. Although an indefatigable critic of Rousseau, she yet constantly gives evidence of his influence. She was the author of *Théâtre d'éducation* (1779); *Adèle et Théodore* (1782), also known as *Lettres sur l'éducation*; *Les Veillées du château* (1784). A prolific writer, she was the author of nearly one hundred volumes. In addition to those noted above, her works on education include: *Discours sur la suppression des couvents de religieuses et sur l'éducation publique des femmes* (1790); *Discours sur l'éducation de M. le Dauphin* (1790); *Leçons d'une gouvernante à ses élèves, ou fragments d'un journal qui a été fait pour l'éducation des enfants de M. d'Orléans* (1791); *Discours sur l'éducation publique du peuple* (1791); *Nouvelle méthode d'enseignement pour la première enfance* (1800); *Projet d'une école rurale pour l'éducation des filles* (1802); *Les Dimanches, ou Journal de la jeunesse* (1816), published for only one year. **GENOA, UNIVERSITY OF**—See ITALY, EDUCATION IN

**GENTRY AND NOBLES, EDUCATION OF**—The close connection between education and politics has been recognized from the time of classical antiquity. Plato in his *Republic* and Aristotle in his *Politics* laid down the principle of the vital importance to the state of the education of children. Throughout the Middle Ages, the education of the actual kings, princes, and other governors of the state was recognized as an essential preparation to the child, who was a prospective ruler. Treatises commonly described the duties of princes, and logically this

led to dealing with the question of preparation for such duties. Thus, Thomas Aquinas wrote the *de Regimine Principum*. Oecleve produced his *Regiment of Princes*. Italy was especially distinguished by its books on political philosophy, in the fifteenth century Pontano writing *de Principe*, Beroaldo the *Libellus de optimo Statu et Principe*, and Francesco Patrizi his *de Regno et Regis Institutione*. In England John of Salisbury wrote his famous *Polycraticus*, and in 1531 Sir Thomas Elyot (*q.v.*) wrote the *Governour*. This last-named work is particularly noteworthy because a considerable portion of the book is taken up with the question of the education of the prospective Governour. This illustrates the connection which was felt by the older writers between education and political philosophy. If the prince or the governor, or by whatever name the ruler was called, had to rise to the responsibility of governing a country, then it is clear that the welfare of the nation is dependent largely upon the excellent training culture, or, in a word, the education of the prince or ruler. So that in the days of an absolute Tudor monarch, Erasmus wrote, as a matter of vital concern, an educational treatise on *The Institution of a Christian Prince*, and throughout the sixteenth, seventeenth, and eighteenth centuries, numberless educational treatises concerned themselves with the education of the prince.

After the devastating Wars of the Roses in England, the power of the old nobility was wrecked, and under the Tudors a new nobility and gentry arose, roughly speaking founded upon personal merit and achievement. The merchant adventurers, sailors, and warriors came into the higher classes concurrently with the development of Protestantism. As the new order of aristocracy came into power in the state, the books on education concerned themselves with the education of nobles. Thus Laurence Humphrey (*q.v.*) wrote his *Nobles or Of Nobility*, and it is interesting to note that he had written it first in Latin (as *Optimates* in 1560), showing that the Renaissance spirit was one which could assume that a politico-educational work to be read by nobles must be written in Latin. The fact that he also wrote it in English shows the advancing place of the vernacular also with the upper and governing classes. But the implication was that, as formerly, the education of the prince was the most important political aspect of education, and the desirability of the education of the nobles as well as princes was recognized as a national asset. In 1555 was published the anonymous *Institution of a Gentleman* (*q.v.*), and the significance is that the “gentleman” was becoming a more noticeable element politically, and, therefore, nationally claimed a higher education. On this theory, the broader the basis of the governing power, the wider will be the demand for education, to meet the required responsibility, until in an age of demo-

cratic government the demand will extend to universal education since, the power being in the hands of the people, there, too, must be placed the education and preparatory instruction to meet the responsibility. Another element in the education must be noted — that the “gentleman” stood in opposition to the “poor student.” Accordingly, sometimes “the gentleman” stood outside the university and public school system, was educated at home by a private tutor, and afterwards, even if he went for a time to one of the universities, went also to one of the Inns of Court, and of course traveled on the grand tour of Europe. The education of the gentleman, therefore, became distinguished by its greater breadth. At the period of the Renaissance, too, the tradition of Italian models set in, as the revival of learning for Europe had its origin in Italy. This was at the very time that the courts of Italy had developed a standard of courtliness and chivalry far in advance of what was found elsewhere. The consequence was that England looked to Italy for the type of nobility and gentlemanliness founded on what obtained at Urbino, at Mantua, and elsewhere. The effect of these courtly ideals in education may be seen in the educational thought of Vittorino da Feltré (*q.v.*) and Guarino da Verona (*q.v.*). These ideals found literary expression in Baldassare Castiglione's *Cortegiano*, 1528 (*q.v.*). Roger Ascham (*q.v.*) in the *Scholemaster* (1570) says of this book, “To join learning with comely exercises Conte Baldesar Castiglione in his book *Cortegiano* doth trewely teach, which book advisedly read and diligently followed but one year at home in England would do a young gentleman more good, I wisse, than three years' travel abroad in Italy.” Castiglione's *Cortegiano* was the climax of books on manners, which were of long standing (see MANNERS AND MORALS). The *Cortegiano* was translated into English in 1561 by Sir Thomas Hoby. Sir John Cheke wrote a letter to Hoby on the use of English in connection with his translation. (See CASTIGLIONE, BALDASSARE.)

After the *Governour* of Sir Thomas Elyot in 1531 the next books to notice are the *Institution of a Gentleman* (1555) and Laurence Humphrey's *Nobles*, 1560 (*q.v.*). In 1561 Sir Nicholas Bacon drew up *Articles for the Education of the Queen's Wards*, and about 1572 Sir Humphrey Gilbert planned his Academy for the Queen's Wards and other youth of nobility and gentlemen. (See *Queen Elizabeth's Academy*, Early English Text Society, 1869.) In 1570 “T. B.” (? Thomas Blundeville, *q.v.*) translated into English John Sturm's *Nobilitas literata or A Rich Storehouse or Treasury for Nobility and Gentlemen*, and in the same year Blundeville translated from the Italian of Alfonso d'Ulloa the *Prince of Federigo Furio, a Spaniard*. It will be remembered that Roger Ascham's *Scholemaster* (1570) and John Lyly's *Euphues* (1577) are largely concerned with the

education of gentlemen. Less known is an anonymous tractate in 1577 entitled *Civile and Uncivile Life: a Discourse very profitable, pleasant, and fit to be read of all Nobilitie and Gentlemen Where in forme of a Dialogue is disputed what order of lyfe best bescemeth a Gentleman in all ages and times, as well for education, as the course of his whole life to make him a person fit for the publike service of his prince and country, and for the quiet and comynesse of his own private estate and callinge*.

In 1595 William Jones translated the treatise of Giovanni Battista Nenna, under the title *Nennio Or a Treatise of Nobility, wherein is discoursed what true Nobility is, with such qualities as are required in a perfect Gentleman*. Nenna maintains that a man becomes noble by the nobility of his mind, and that men and women equally become noble by learning. In 1598 J. Keper translated Count Hanniball Romei's *Courtier's Academy*, the representative book of the court of Ferrara. The later most representative English books are Henry Peacham's (*q.v.*) *Compleat Gentleman* (1622) and Richard Brathwaite's *English Gentleman* (1630) and *English Gentlewoman* (1631), the former dealing with topics from the point of view of the Cavaliers, whilst the latter are permeated with puritanic manners and morals. These ideals were to some extent combined in the *Gentleman's Calling*, 1659, perhaps the most popular book on the training of the religious gentleman which appeared in the seventeenth century. This book was followed in 1673 by the *Ladies' Calling*, which has considerable interest in the history of the education of gentlewomen. There is much controversy as to the author of these books. They have often been ascribed to Dorothy, Lady Pakington, but Mr. Macray in the *Dictionary of National Biography* (in his article on the life of that lady) considers it is more probable that they were written by Richard Allestree, an Oxford tutor.

In 1661 appeared Clement Ellis's *Gentile Sinner, or England's brave gentleman characterised in a letter to a friend both as he is and as he should be*, 2d ed., 1661 (Oxford), from a thoroughly puritan point of view. In 1678 John Gailhard (*q.v.*) wrote his *Compleat Gentleman*, which probably gives the best account of the grand tour as made by gentlemen of the time. About 1728 Daniel Defoe (*q.v.*) wrote his *Compleat English Gentleman*, first published in 1890, edited by Dr. Karl Bulbring, which is noticeable for its readiness to omit Latin from the studies of the gentleman. “You may,” says Defoe, “be a gentleman of learning, and yet reading in English may do for you all that you want.” After the end of the seventeenth century with the beginning of the establishment of charity schools (*q.v.*) and the development of technical and trade schools the extension of the term “gentleman” had widened out greatly, so that the idea of a “liberal” educa-

tion and a gentleman's education became much more approximated.

The distinction between the education of the scholar and the gentleman in earlier times is perhaps best indicated by saying that after the Renaissance the progress of the academic centers was mainly in the direction of the development of the subjects of the medieval *trivium*, viz grammar, rhetoric, and logic, whereas the great intellectual advances of the sixteenth and seventeenth centuries introduced what are called "modern subjects," *e g* mathematics, natural sciences, vernacular languages, foreign and English. These subjects were almost entirely ignored by the universities and grammar schools. Such "outside" subjects, together with physical exercises, such as riding the great horse, fencing, gymnastics, were precisely the subjects studied by the nobility and gentry, as is shown in the proposed curricula of the projected Academies (see GILBERT, SIR HUMPHREY, KINASTON, SIR FRANCIS, GERBIER, SIR BALTHASAR, ACADEMIES, COURTLY). We are therefore driven to the conclusion that it is to the records of the education of the gentleman and the nobleman that we must refer to trace the progress of the growing width of the curriculum rather than to the history of the universities and the grammar schools.

It is important to notice that the development of professional education — *e g* the lawyer, the physician, and the clergyman — was often along the lines of the modern subjects and thus by attraction came into the educational circle of noblemen's studies much more readily than into that of the university man as such, — the physician's studies, for instance, directly affecting the development of botany and zoology, which often were included in the nobleman's curricula. When England became richer after the increase of trade, consequent on the expansion of Queen Elizabeth's reign, the ranks of country gentlemen increased, and open-air pursuits and knowledge similarly developed, nobility and gentry joining in common studies, so that cultured gentlemen of the type of John Evelyn (*qv*) and the members of the Royal Society welded together still further professional and gentlemanly studies, until at last the universities found the pressure of inclusion of modern subjects too great to resist, if they were not to lose the students preparing for professional life.

The importance of the training of the gentleman in history and geography must not be overlooked. It is not only that all the writers on gentlemen's education prescribe these subjects as gentlemen's studies, but the writers and developers of the subjects were for the most part of the gentleman class. Both in history and in geography, also, it is to be noted that the beautiful folios, in which these subjects were printed, especially when illustrated with engraved pictures and maps, were expensive productions and could only circulate amongst men

of means, and of these the nobles and the gentry were the chief book buyers, scholars contenting themselves mainly with Aldine octavos or Elzevir duodecimos, with only occasional folios, and these chiefly of theology or classical writers. Suggestions on the youth's studies by writers like Francis Osborn in his *Advice to a Son*, 1656, J. B. (Gent) in *Heroic Education* (*qv*), and William Higford in his *Institutions*, 1658, illustrate the permeation of the gentry class by that time with a belief in the necessity of knowledge in history and geography.

Two other names deserve mention in the development of the education of the gentleman, — one in England and the other in the United States. Lord Chesterfield (*qv*), (1694–1773) and George Washington (1732–1799). In his famous *Letters to his Son*, Lord Chesterfield lays down the laws of worldly success for the young nobleman or gentleman. The youth's education was to be summed up briefly as good breeding.

Every detail of study, of conduct, of life, was calculated in the interests of worldly success. Samuel Johnson summarized the *Letters* in the criticism, "Take out the immorality and the book should be put into the hands of every young gentleman, for it would teach elegance of manners and easiness of behaviour." (See CHESTERFIELD, LORD.)

The *Rules of Civility* is only a commonplace book exercise of George Washington, written when he was fourteen or fifteen years of age. These *Rules* have been reprinted and edited by the late Mr. Moncreux D. Conway, who suggests that the reading and writing of them probably had effects upon the development and character of Washington. He shows that the *Rules* copied by Washington were the work of a Jesuit, from the College of La Flèche, which was published in 1595, called *Bienséance de la Conversation entre les Hommes*. This was translated into Latin in 1617 by Leonard Périn, and was published in English as *Youth's Behaviour or Decency in Conversation amongst Men*, by Francis Hawkins, in 1646, said to have been translated by him at the age of eight years (See MANNERS AND MORALS, EDUCATION IN). From this book, Dr. Conway urges that Washington was taught that "all good conduct was gentlemanly, all bad conduct ill-bred."

The eighteenth-century training in gentlemanly conduct is probably represented somewhat leniently by the relatively high (!) standard of Lord Chesterfield. The reaction in the earlier part of the nineteenth century is shown by the reintroduction of the highest standards of gentlemanly training in the English public schools. The greatest figure of this period was Dr. Thomas Arnold (*qv*) of Rugby. His standpoint is represented by his *dictum* "It is not necessary that Rugby should have three hundred pupils, but it is necessary that it should have scholars who are Christian gentle-

men" The English public schools since his time have largely developed physical training through games, but whether concerned with intellectual aims or with that of the other features of school life, there can be no question that these schools have been, and are, permeated with the ideals of producing gentlemen, in the sense of requiring the code of honor of "playing the game," in every activity of life In certain respects they have entered on the physical side into something of the old chivalric ideals, and occupy the place in English life to-day which the old Academies of Sir Humphrey Gilbert and Sir Francis Kinaston proposed to do, but failed to effect, for the training of gentlemen, in the sixteenth and seventeenth centuries

## GEOFFREY THE GRAMMARIAN (fl 1440).

— An important figure in the age immediately before the introduction of printing, not because of the scholarliness of the book associated with his name, but because the production of that book showed that the tide was turning, that the desire for learning was once again awakening in England, and that a new educational method was necessary About the year 1440 a friar-preacher anchorite of Lynn in Norfolk, called Geoffrey, issued for manuscript circulation a volume entitled *Promptuarium Parvulorum Clericorum*. It was not the work of a scholar in the real meaning of that term. It was written by one whom the Anglo-Saxon Canons would have termed a "half-learned" person for the use of the still less learned. The book was a kind of English-Latin dictionary in which the English word is interpreted by one or more Latin words whose gender or declension, etc., is noted, while parallel English meanings are given. It is indeed curious that a book which did not pretend to scholarship should, even when the new learning and the new grammars had appeared and in the teeth of the condemnation of Erasmus, have more than held its own. The *Promptuarium* was first printed in 1499 by Pynson.

Julian Notary published an edition in 1508, and Wynkyn de Worde issued no less than seven editions between 1510 and 1528. The book was English-Latin, and for that reason was of real help to beginners. The use of English in a grammar or wordbook was felt to supply a fundamental need, and was rapidly adopted by the new grammarians. Thus John Stanbridge, John Holt, William Lily, and Robert Whyttington led the new movement and adopted the new educational idea evolved by the educational necessities of the "half-learned" monk Geoffrey. In the old grammars or "donats" the use of English was forbidden in school time. It may be said that Geoffrey's work inspired all the school books of the transition period and created a new didactic method.

**GEOGRAPHY — History of the Teaching of** — The practical and theoretical knowledge of geography extant at any given time constitutes a clear limit to the possibilities of its being taught, but the extreme importance of the practical side has insured throughout the course of history a greater approximation of teaching to the actual knowledge of the age, than in many subjects. Military and naval commanders found it necessary, and administrators required to know it both for home and foreign affairs. The extension of Greek influence through the establishment of colonies, and by enterprising navigation, made at least the Mediterranean Sea well known.

The first to systematize geography as a subject was Hecataeus of Miletus (fl. 520 B.C.), who thus became the Father of Geography as Herodotus was the Father of History. Herodotus, however, by his travels was enabled to introduce casually, into his histories, much geographical information as to continents, rivers, mountains, climate, products etc., of the countries he had visited, as well as descriptions of the tribes of foreign countries. The famous expeditions of Alexander the Great opened up knowledge and experience to Egypt on the south, the Caspian Sea on the north, and Persia on the east, revealing the "wealth of Ormuz and of Ind," and furnishing material for the imagination throughout the centuries. The greatest Greek geographer was Polybius (c. 210-128 B.C.), who traveled in Libya, Spain, and Gaul so as to "remove the ignorance" with regard to those lands. His opinion as to Hannibal's route across the Alps was based on actual travel and inquiries on the spot. He asserted that travel is necessary for the historian and geographer, and he clearly saw and illustrated in his histories the importance of geography, both physical and descriptive, to

intelligent study of history. The subjugation of so large a part of the world by the Romans gave particular impetus to the extension and intensification of geographical knowledge. Cæsar's *Commentaries* offer copious illustrations of the effect of conquests on geographical observation and interest. The explorations of Posidonius the Greek (130-50 B.C.) were of great importance in developing the knowledge of physical geography. But the great work of antiquity is the *Geography* of Strabo (c. 63 B.C.-c. 23 A.D.), which not only gives a complete survey of the geographical knowledge of his times, but also supplies an account of the preceding writers on the subject. Strabo is a truly comprehensive geographer, taking up mathematical, physical, descriptive, and historical aspects. He traces the influence of the physical features of a country on the character of inhabitants and on the course of the history of the country.

The other ancient writers on geography who require mention are Pomponius Mela, Pliny, Dionysius, and Ptolemy. The *de Chorographia* of Mela was a popular account of geography, and important, not for its contributions to learning, so much as from the fact that it remained a scholar's textbook of geography up till, and even beyond, the sixteenth century. Pliny's *Historia naturalis* (79 A.D.) had a section on geography, but it was very much a statistical geography abounding in names, without anything of the philosophical outlook of a Strabo. Dionysius Periegetes (reign of Domitian) wrote a geographical poem. From the point of view of the history of geographical teaching this poem of 1189 Greek hexameters has an importance altogether incommensurate with the commonplace nature of its geographical information. Claudius Ptolemy, who wrote in Greek his famous treatise on geography (c. 150 A.D.) probably at Alexandria, ranks as the greatest mathematical geographer of antiquity, and the ancient view of the solar system as revolving round the earth is known as the Ptolemaic system, in contrast with the modern view called after Copernicus. It was as an astronomer that Ptolemy showed conspicuous ability, and the great vogue of his books secured the alliance of astronomy and geography through the Middle Ages, and part of the Renaissance. It was not till the times of the great discoveries of the sixteenth century that geography became differentiated from astronomy, the combined studies being commonly known by the name of Cosmography. Ptolemy made the great change in map drawing by introducing the system of projection, recognizing the spherical nature of the earth, representing lines of latitude by parallel *curves*, whereas previously they had been denoted by parallel *lines*. (See MAPS.) Besides the treatment of mathematical geography and of maps, the rest of Ptolemy's *Geography* contains tables giving the latitude and longitude of the different places

named in his various maps, and noticing the boundaries of countries, etc. The rest of the work is mainly astronomical.

The most intensive geographer of antiquity was Pausanias, a contemporary of Ptolemy, and author of an *Itinerary of Greece*, which gives a full account of Greek cities and sacred places, and noteworthy points on the routes from one to another of these, together with the legends and memories connected with each. C. Julius Solinus (third century A.D.) wrote a section on geography in his *Memoirabilia*, which had nothing geographically original, and but little that is not contained in Pliny, whence he was known as the "Ape of Pliny." Nevertheless, the writers of the Middle Ages who wrote their encyclopedias, such as Isidore of Seville (q.v.) in his *Origines* (seventh century) and Brunetto Latini (twelfth century) in his *Tesoro*, borrowed directly in their geographical section from Solinus. In the fifth century A.D. Paulus Orosius in his *Histories*, a collection of annals of universal history, wrote an outline of universal geography which was very popular with medieval authors and teachers.

The geographical writers of antiquity, Herodotus, Polybius, Strabo, Pomponius Mela, Pliny, Dionysius, Ptolemy, Pausanias, all of whom wrote in Greek, were lost to the Middle Ages. During the Renaissance period, and none the less because they wrote in Greek, they were restored to general knowledge, and with their renewed study ancient geography became a matter of serious study in the schools, both in the Latin translations and in the Greek original, ancient geography thus found a place in schools long before modern geography.

In the Middle Ages the development of geographical knowledge progressed slowly. Its progress in the period up to the first crusade of 1096 is chiefly connected in the earlier part of the period with the religious cosmographies or geographies, and in the latter part with the explorations, discoveries, and conquests of the Scandinavians. In the earlier period, as far as Christian countries are concerned, the cause of geography was bound up with the pilgrim-travelers, the convent maps, and the religious impulses which suggested the conversion of the heathen. The gain to exact knowledge was not great; the chief result was the development of geographical myth. The introduction of the Scandinavian element into European countries brought a vigor and enterprise, which communicated themselves in every direction, leading both to geographical discoveries as far as America and the Northern seas, and to a rereading and more direct knowledge of that which had already been noted. The work of Arabs in geography, reaching its height in the ninth century, included translations of the old Greek geographers, astronomical calculations, and even observatory work. Arab explorers traversed much of Southern and Central Asia, Northern Africa, and the

Mediterranean Sea coasts From these experiences, with the wonder element thrown in, arose literature such as that of Sinbad the Sailor Chinese geographical enterprise also was noteworthy The Crusades led to all kinds of commercial, diplomatic, missionary, as well as pilgrim, travel, from which an immense acquisition resulted to geographical knowledge and tradition Commerce between East and West Europe, between Mediterranean countries and northern countries, developed into a secular organization of merchandise, which produced an uneclesiastical and more scientific geography Asia was explored by men like the merchant Marco Polo and Friar Odoric in the thirteenth century, and in the fourteenth century the Catalan Atlas (1375) attained a highly creditable form of thoroughness, and from that time the production of more exact maps marked the possibility of the transition of geography into an exact science Civilized Europe in the fourteenth century had discovered the use of compass, astrolabe, time-piece, as well as maps The art of navigation went forward by leaps and bounds Oversea adventure vied with overland enterprise until in the first quarter of the fifteenth century Prince Henry of Portugal promoted geographical journeys, and opened up the era of Portuguese enterprise which culminated in 1486-1499 in the voyage round the Cape of Good Hope to Calicut by Diaz and Da Gama, and the discovery by Columbus of America In 1511 Portuguese navigators had reached by the Eastern route the Molucca Islands, and in 1519 Magellan attempted the journey to them by the Western route Sir Francis Drake circumnavigated the globe in 1577-1580, and Vitus Behring discovered the strait which separates America and Asia Thus by the end of the sixteenth century, the main features of the Earth had been described, the continents had had their contours defined in maps; travels and discovery had made known country after country, people after people, and geography had come to its own, by practical experience Much remained, of course, to be done in the way of filling up, particularly in the seventeenth century, but by the end of the fifteenth century and in the sixteenth century geography had reached the stage of self-consciousness Exploration had provided itself with instruments and methods, so that by that time geography may be said to have become a science in the sense that earth knowledge became an established subject of study by deliberate methods, and the ascertained knowledge thence derived became available for dissemination, and brought the subject into the pedagogic survey, at any rate, for those who were attracted to the study of the advance of civilization In England, from the time of Drake onwards, there was always a school of navigation in training, where students made geography in some form or other the study of their

lives, and there was from the time of the collection of travels of Ramusio in 1550, of Hakluyt, 1598-1600, and Purchas's *Pilgrims*, 1613-1625, a solid body of writers and readers of travels

Though the development of geographical knowledge had steadily advanced throughout the Middle Ages, the literature of the subject is almost a negligible quantity It was inextricably mixed up with biblical, classical, and legendary material Only one book stands out as important, viz., Marco Polo's *Book concerning the Kingdoms and Marvels of the East*

In the early Renaissance period those works only could be regarded as literature which belonged to Roman and Greek antiquity In school teaching, throughout the sixteenth and seventeenth centuries, the study of ancient geography certainly almost entirely absorbed the attention of the teachers, as far as this subject was concerned For the most part, the teachers confined themselves to the texts of ancient geographers, — particularly Pomponius Mela, Ptolemy, and Dionysius Periegetes, and the astronomical work of Proclus Of the ancient geography textbooks, a printed copy of Pomponius Mela was sold in England as early as 1520 In 1585 Arthur Golding translated Pomponius Mela into English, and did the same service for the *Polyhistor* of Solinus Of Dionysius there was an English translation in 1572 by Thomas Twyne A Greek text of Dionysius was published at Eton c 1607 In 1658 a most elaborate edition of Dionysius was furnished *ad usum tyronum* with Greek text and Latin translation and a most voluminous commentary, by William Hill, M A, of Merton College, Oxford, and afterwards schoolmaster at Dublin Philemon Holland's translation of Pliny's *Historia naturalis* was published in 1601, the second edition in 1634, and this was recommended for school libraries by Hoole in 1660 A comparative study of various textbooks and authorities enabled Cluverius in 1624 to produce a geography of ancient Italy, which Hallam describes as "the great repertory of classical illustration in this subject" The only other contemporary author's classical geography that needs mention is Ferrarius' *Lexicon Geographicum, Poeticum, et Historicum*, an edition of which was published in London in 1657 But there were, even at this period, men of larger vision in geographical study In 1511 Erasmus (*q.v.*) advocated the study on account of its value in reading history and the poets The school-teachers, however, supported Erasmus in the view that the chief importance of geography was to illustrate and elucidate classical writers and to provide copiousness of phrase in the descriptions introduced into themes and exercises in Latin and Greek writing In 1523 Vives (*q.v.*) recommended the pupil to read Strabo and Ptolemy, though in reading the latter the lately introduced and more exact maps were to be preferred Vives

however, further wishes the pupil to add the "ancient discoveries" in the East and West "from the navigation of our people" (the Spanish) and the collections of travels of Peter Martyr and of Raphael of Volterra, so that he may be regarded as the first advocate of the teaching of modern geography. In 1531 Sir Thomas Elyot (*qv*) in the *Governour*, requires the pupil to be taught geography, to prepare him for understanding histories. He is an enthusiastic believer in the value of pictures, plans, and maps, and insists that cosmography is a necessary study for "all noble men." In 1560 Laurence Humphrey (*qv*) in the *Nobles*, speaks of geography as a study that brings "great delight and profit." In 1622 Henry Peacham (*qv*) in his *Compleat Gentleman* recommends cosmography as a "science at once feeding both the eye and mind with such incredible variety and profitable pleasure, that even the greatest kings and philosophers have bestowed the best part of their time in the contemplation thereof at home" (See GENTRY AND NOBLES, EDUCATION OF). In the same year Robert Burton (*qv*), in his *Anatomy of Melancholy*, speaks of the pleasure in studying geographical maps and praises those of Ortelius, Mercator, Hondius. His bibliographical list of geographical books includes books of cities by Braunus and Hogenbergius, descriptive works by Maginus, Muster, Herrera, Lact. Merula, Boterus, Leander, Albertus, Camden, Leo Afer, Adricomius, Nic. Gerbelius, etc.; the famous expeditions of Christopher Columbus, Amerigo Vespucci, Marcus Polus, the Venetian, Lod. Vertomannus, Aloysius Cadamustus, etc. He goes on to enumerate the accurate diaries of Portugals, Hollanders, of Bartison, Oliver à Nort, etc.; Hakluyt's *Voyages*, Peter Martyr's *Decades*, Benzo, Lerijs, Linschoten's *Relations*, those *Hodæporicons* of Jod à Meggen, Brocard the Monk, Bredembachius, Jo. Dublinus, Sandys, etc., to Jerusalem, Egypt, and other remote places of the world. Then he names the Itineraries of Paulus Hentzner, Jodocus Sincerus, Dux Polonus, etc. — with the reading of Bellomus, *Observations*, P. Gillius' *Surveys*. He then refers to "those parts of America set out, and curiously cut in pictures by Fratres a Bey." Such a list as that of Burton shows the vast development of geographical literature by 1622, one hundred and thirty years after the discovery of America. Among other prominent advocates of the teaching of geography in schools were Comenius (*qv*) in the *Great Didactic*, Milton (*qv*) in the *Tractate*, and Locke in *Thoughts concerning Education*.

The development of geographical theory might be illustrated by a comparison of the first modern geography in England, viz the *Cosmographical Glasse*, 1559, a very creditable first production, and the *Geography* of Nathaniel Carpenter (*qv*), fellow of Exeter College, Oxford, in 1625. In the latter work we have a comprehensive volume of mathematical geog-

raphy in the first part, while in the second part the connections of geography are carefully traced in other realms of inquiry, and the idea of "human" geography is almost as clearly grasped as in a present-day treatise.

Peter Heylyn had published in 1621 his *Microcosmus, or a Little Description of the Great World*. After spending over thirty years of further work, he produced in 1652 his *Cosmographie, containing the Chorography and History of the whole World and all the principal Kingdoms, Provinces, Seas and Isles thereof*. This is a thick folio, with 1100 well printed, matterful pages, a handsome volume full of history and geography for all the known parts of the world. It takes up almost every phase of geography, in profuse detail. It appeals to those who wish to read the Holy Scriptures by its sacred geography, to astronomers, to physicians (who may learn from geography the different tempers of men's bodies according to the climes they live in), to statesmen, to merchants, mariners, and soldiers. Cosmography, with Heylyn, includes natural and civil history, descriptive geography, and mathematical geography. The frequency of reprints of this huge and costly folio, well supplied with maps and illustrations, shows the vogue of the subject, especially when we bear in mind the costliness of production and the leisure required for reading it. It is a gentleman's book, geography was particularly a gentleman's study, and the reprints of Heylyn in 1657, 1662, 1666, 1670, 1674?, 1677, 1682, 1703, are an indication of the enormous development of the class of "gentlemen" in Tudor and Stuart times.

Returning to the advocates of the teaching of geography, J. A. Comenius in his *Great Didactic*, written about 1631, includes in the curriculum of the vernacular school "the most important facts in cosmography, such as the spherical shape of the heavens, the globular shape of the earth suspended in their midst, the tides of the ocean, the shapes of seas, the courses of rivers, the principal divisions of the earth, and the chief kingdoms of Europe, but in particular, the cities, mountains, rivers, and other remarkable features of their own country."

Sir William Petty (*qv*) in 1647 suggested that in the equipment of his *Gymnasium mechanicum* there should be the fairest globes and geographical maps, "and he wished the institution to be an epitome and abstract of the whole world." In 1649 George Snell in his *Right Teaching of Useful Knowledge* directed that the pupils in the English School should study the "excellent art of cosmography" and "delightful use of topography" and in 1650, John Dury (*qv*) in his *Reformed School*, suggested that an outline of geography ought to be taught in schools. In 1660, in the *New Discovery of the old Art of Teaching Schools*, Charles Hoole suggested that "in the uppermost story of the school there should be a fan,

pleasant gallery wherein to hang maps and set globes, and to lay up such varieties as can be gotten in presses or drawers, that the scholars may know them"

Of actual geography teaching in academic institutions in England the first record naturally enough is that of Richard Hakluyt (*q.v.*) who claimed that he was "the first to show the new lately reformed maps, globes, spheres, and other instruments of this art for demonstration in the common schools" It must be observed, however, that though Hakluyt claims to be the first teacher of modern geography in England, yet in the ordinances of Shrewsbury School, drawn up in 1571 by the bailiffs of the town, provision is made that "from the stock remnant there should be provided a library and gallery furnished with all manner of books, mappes, spheres, instruments of astronomy, and other things appertayning to learning," and in 1596 the school had obtained "Mullinax his territorial globe in a frame with a standing base covered with greenish buckram" In 1597 the statutes of Blackburn grammar school state explicitly that "the principles of arithmetic, geometry, and cosmography, with some introduction into the spheres are profitable" In Laud's transcript of the studies of Westminster School 1621-1628 in the IVth and VIIth Forms: "After supper (in summer time) they were called to the Master Chamber (specially those of the VIIth Form) and there instructed out of Hunter's [*i.e.* Hunter's] *Cosmographie* and practised to describe and find out cities and countries in the mappes" This was the *Cosmographie* (in Latin) of John Hunter, which contained textbook, atlas, and index Instruction was probably given at Winchester College in geography, for in the Bursar's book for 1656-1657 is the item £117 6 for a *Mappa Mundi* It is probable that in all these cases the systematic geography taught was that of ancient Greece and Italy, as illustrative and elucidatory of the classical authors, and for composition writing in Latin prose and verse

It is not improbable that some schoolmasters outside of the systematic curriculum may have been interested in and taught geography, as, for instance, John Langley (*q.v.*), head master of St Paul's School, who is described as a "historian cosmographer and antiquary", William Camden (*q.v.*), whose topographical knowledge of England was unique, head master of Westminster School, Thomas Farnaby (*q.v.*), master of the largest private school in England in the first half of the seventeenth century, who had in 1595 accompanied Sir Francis Drake on his last voyage

Outside the schools, Hakluyt has already been mentioned at Oxford In 1654 John Webster (*Examination of Academies*) says that in the universities geography, hydrography, chorography, and topography were usually taught, and he names the textbook used as that of

Nathaniel Carpenter, but this was probably the mathematical part, rather astronomical than geographical The projectors of academies, Sir Humphrey Gilbert (*q.v.*), in 1572, Sir Francis Knaston (*q.v.*), in 1635, and Sir Balthasar Gerbier (*q.v.*), in 1648, all included cosmography as part of the proposed curriculum

With the great advance of maritime discoveries and with the constant emigrations to New England, a great naval service arose, and the preparation of youths in so much of geography as pertains to navigation became necessary Boys were apprenticed in large numbers to sea captains, serving especially in the Indian navy In 1673 the Mathematical School in Christ's Hospital was founded with a view to preparing boys directly for sea service, in such subjects as mathematics, navigation, etc According to the King's ordinance the Governors were to furnish the necessary "Books, Globes, Mappes, and other Mathematical instruments" At sixteen years of age or before, if the master of Trinity House saw fit, the boys were to be bound apprentice for seven years to the captain of some ship in the royal or merchant service In 1681 the navigation class book was issued It was written mainly by Sir Jonas Moore, assisted by the famous Flamsteed and Halley It was entitled *A New Systeme of the Mathematicks* and contained sections on mathematical subjects, as well as cosmography, navigation, the doctrine of the sphere, astronomical tables, and geography The latter is described as a "description of the most eminent countries and coasts of the world, with maps of them and tables of their latitude and longitude" The geography thus was prevailingly mathematical, and it is interesting to note that one of the Governors of the School, and a member of the Committee at the Visitation of 1697 was Sir Isaac Newton Many public schools arose throughout the country in imitation of the Mathematical School of Christ's Hospital and not a few private schools, where navigation received special attention

In 1674 Joseph Moxon, hydrographer to the King, published the third edition of his *Tutor to Astronomy and Geography*, dedicated to Samuel Pepys, "not as what you need but what may prove an ease to your memory" Though the official hydrographer, Moxon introduces a section on astrological problems The geographical section is certainly mathematical

Geography was taught, curiously enough, by foreign language masters Thus Guy Miège (*q.v.*) in 1678 describes himself as professor of the French language and of geography He speaks of geography as a subject becoming a young gentleman, and says he doubts not the subject "will take root amongst the nobility and gentry of England as it hath in other nations; especially since the war began," and he

offers to teach geography either in French or in English. In 1682 he wrote a *New Cosmography or Survey of the Whole World*. Similarly in 1769, M. Jacques de Lavaud was a teacher of languages and of geography. It seems likely, therefore, that both French and geography received stimulus in their teaching from the Huguenot influence in England.

In the eighteenth century the development of the chronometer introduced more exactitude -- in the fixing of the position of distant places. Surveys of coast lines and interiors become more exact, and measurements of the earth more reliable.

In 1729, the Fishmongers' Company in London presented their grammar school at Holt, in Norfolk, with "a valuable and useful library, not only of the best editions of the Classics and Lexicographers, but also with some books of Antiquities, Chronology, and Geography, together with a suitable pair of globes."

In the century which intervened between Locke and Vicesimus Knox (*qv*) geography in England received attention practically as well as theoretically. This was particularly the case in private schools rather than in the public schools of England. Thus John Randall, who conducted a school at Heath, near Wakefield, in 1744, and afterwards removed to a school at York in 1765, wrote a "system" of geography, a comprehensive dissertation on the creation and various phenomena of "the terraqueous globe," as it consists of "subterraneous waters, mountains, valleys, plains, and rivers," with an hypothesis concerning their causes. It further contains a description of all the empires, kingdoms, etc., of the world, drawn from ancient and modern history, and some of the most celebrated voyages and travels. Statistics are comprehensively given of the "present state" of the various countries and full details offered as to climate, government, laws, policy, trade, revenues, forces, curiosities, population, character, religion, customs, ceremonies. In 1753 another private schoolmaster, J. Burgh, recommends in the study of geography the following textbooks: Randall's *System of Geography*; Harris' *On the Use of the Globe*, the *Geographical Dictionary*; Anson's *Voyages*, and Salmon's *Geographical Grammar*. Of this list, Harris's *Geography* was the book of longest and widest vogue on the subject. The second edition is dated 1712. It proceeds by question and answer, and it is the first school textbook (apparently) of purely descriptive geography, and distinctly an interesting and helpful book for the learner. In 1746 was published the third edition of an *Introduction to Geography* on the same lines as that of Harris, written by J. Cowley, "geographer to his Majesty," a work which is apparently the first general modern geography explicitly stated to be "designed for the use of schools." These textbooks of Harris, Cowley, and Randall are more modern in scope and outlook

than the later *Guides to the Use of the Globes*, the series beginning with that of Daniel Fenning in 1760, and continuing to the more matterful and interesting *Exercises on the Globe* of William Butler in 1814, designed "for the use of young ladies." At the beginning of the nineteenth century, the use of the globe was an acknowledged part of the curriculum of all the private schools and academies for young gentlemen and young ladies, although the teaching was mainly informational, and had little mental discipline in it.

Two points especially should be noted in tracing the history of geography teaching. First, its development has taken place outside of the recognized public schools system, chiefly in private schools. Second, arising in the mixed subject of cosmography it has become differentiated as earth knowledge, and its original partner, astronomy, in the portions which have especial reference to our earth, curiously enough, and not altogether advantageously, has been ousted from the study, even in outline, of the great masses of (at any rate) British children. In the teaching of geography itself, however, within the last decade modern aims and methods have improved almost more remarkably perhaps than in any single subject in England.

F. W.

**Academic Status — Germany** — Geography as a university subject has long had a prominent place in Germany. A long list of eminent names attests to the high position of this science in a nation noted for its scientific achievement. Humboldt, Ritter, Ratzel, and Richtofen stand out prominently among the great geographers that the world has produced, and in the German universities of to-day are included some of the leading geographers of the present time. Geography is a recognized and essential part of the university curriculum, and provision is usually made for the presentation of various phases of the subject by two or more specialists in different parts of the geographic field.

The prominence attained by geography in Germany is the result of a variety of causes, among which is undoubtedly the strong influence of a few powerful men, early in the field, working in a country where centralized authority has had a voice in university development. Doubtless also it is partly due to that keen, clear-sighted recognition of the value of science, in all its phases, which has placed Germany in the front rank in science and has been one of the chief underlying causes for the wonderful industrial development of that country. The scientific spirit, so noticeable throughout the German nation, has encouraged geographical research, thus providing teachers; and where there are inspiring teachers and leaders in research, there are certain to come students to listen and to investigate. There are certainly two other prominent factors which help to explain the importance of geography in the universities of that country. One of these

is the broad intellectual interest of the normal, educated German; the other is the nature of the educational system. Under more or less complete centralized authority a curriculum below the university has been developed in which systematic study of scientific geography has a definite and prominent place. And since the German teacher must know the subject he professes to teach, provision is made in the universities to meet the demand. Further, the breadth of culture among educated Germans is such that it is fully recognized by them that geography is a basal science, an understanding of which is essential to correct interpretation of much of human history and development, and that it is also basal to an appreciation of the distribution of animals and plants and to the industries that depend upon them and upon other products of the earth. Thus it happens that many German students, whose main interest is in other lines, seek a knowledge of scientific geography such as the German university professor can give.

Partly as a result of German influence, geography has now a high place in other continental nations, and what has been said with regard to geography in Germany applies to a greater or less degree to Holland, Switzerland, Austria-Hungary, and France. But in Europe it is almost warranted to state that the importance of geography as a university subject diminishes progressively with the increase in distance from Germany.

*England* — It is a curious fact that in the one nation where the strongest reason for geographic interest would seem to be present — the British — university geography is almost at its lowest ebb. Only within a very few years has any provision whatsoever been made for geography in the great British universities, and then merely in a sort of experimental way in the form of lectureships and readerships, urged and partly supported by geographical societies.

No attempt will be made to consider the question whether the striking contrast between Great Britain and Germany in this respect is in any way ascribable to a difference in scientific spirit or broad scientific culture. There are other more evident and more easily demonstrable causes. One of these is the fact that there is no such centralized educational system below the university; and in the schools geography has no such rank as in Germany. There is, therefore, no such demand for teachers with a university training in geography. A second reason is that the British geologist has taken into his own field some of the best of scientific geography. Therefore some of the most important geographic work published in Great Britain is from the pens of geologists, and is produced as a kind of geological by-product. A third reason for the position of geography in Great Britain, perhaps the result of its world-wide colonial interests, is the fact

that geography there has come to be considered as almost synonymous with exploration. A journey to the Arctic or the Antarctic, a trip across Africa, or an exploration of New Guinea is ranked as more geographical (if we may judge by honors conferred) than an interpretation of a land form, or a scientific study of the geographical relationships of a known area. Geographical publications abound in interesting descriptions of remote regions, little known people, itineraries of journeys, and associated incidents, accidents, and adventures. Such exploratory work while doubtless important, as the accounts certainly are interesting and entertaining, rarely merits the characterization scientific, and is not uncommonly even distinctly unscientific. There is certainly little basis for a subject of this sort to claim a place in the university, and it is by no means improbable that the reputation gained by geography as an essential synonym of exploration is one of the strong reasons why geography has so tardily won a place in the British universities.

Lest this characterization of geography in Great Britain be misunderstood, it may be well to add that there have been scientific geographers of the very first rank. Such names as Lyell, Wallace, and Geikie rank with the world leaders in scientific geography, but they are not, as in Germany, university teachers. The beginning that has been made, notably in the Oxford and Cambridge Schools of Geography, has been admirable and is promising for the future, while the newer universities have also made provision for the higher study of the subject in connection with economics and commercial courses.

*United States* — In America the recognition of geography in the university has been almost as tardy as in England, and for similar reasons. There have been cases where professors of history or of political science, usually with a German university experience, have given brief courses in historical or political or commercial geography to furnish a part of the geographic basis needed by their students. There have been a few cases where chairs of geography were established a generation or more ago, but these instances have been sporadic and have represented no well defined movement toward university recognition of geography.

Perhaps the nearest approach to early recognition of this subject in the university curriculum in the German way was when Guyot (*qv*) was given a chair in Princeton. Agassiz (*qv*) found the American field a virgin one for the introduction of scientific natural history from its European environment, and with his genius, personality, and boundless enthusiasm he laid a foundation upon which the growth of natural history subjects in the American university became assured. Seemingly equal opportunity existed in the field of

geography, and to it Guyot came at Agassiz' suggestion and in 1854 became professor of geography at Princeton, a position which he held until his death thirty years later. Guyot did valuable and important work, but apparently conditions in America were not favorable to vigorous spread of scientific geography; there arose no effective Guyot School and geography in the American university had about the same position at the end of his teaching as at the beginning.

In the meantime, the study of geology (*q.v.*) spread rapidly, and provision is now made for it in every college, while the larger universities have from three to five professors for the subject. This high rank of geology is apparently due in part to the recognized scientific character of geologic study, and in part to the presence of a demand for men with geological training. Geography, on the other hand, has had in America, as in Great Britain, to bear the reputation of being non-scientific, or, at best, little more than a descriptive science. At the same time some of the most thoroughly scientific phases of geography have been annexed by sister subjects, notably by geology. As a result of the confusion thus arising, there has even been a tendency to question whether there is a science of geography, some holding that all that is really scientific in it lies within the province of established subjects, such as geology, zoology, botany, ethnology, history, economics, etc. It is sufficient answer to such a claim to point to the scientific results of continental geographic research, and to the contrast in output on such topics between Germany and England or America, where geography is not so organized as a science.

As in Great Britain, so in America, there has recently come about a change in the status of geography in the university; but the nature and underlying causes of the change have been quite different in the two countries. In Great Britain geography has gone into the university as a result of outside pressure; in the United States it has evolved within the university, primarily as a result of the discovery that much that had previously masqueraded under the term "geology" was really geography, or needed only moderate change to enrich it with the true geographic flavor. Naturally this geography, of geological parentage, is dominantly physical geography or physiography. That it should have made for itself a place in American universities as an offshoot of geological teaching is natural when it is remembered that some of the most significant basal principles of the evolution of land forms have been discovered by American geologists as a by-product of their geological work, — notably by Gilbert and Powell.

To Davis of Harvard, more than to any other one person, is to be credited the evolution of the geographic phase out of the geologic

teaching, and its segregation into a more or less definite branch of science teaching in the American university. Other teachers were, and still are, teaching geography as geology, and some have definitely recognized the fact, — for instance Shaler of Harvard, who in a large part of his broad scientific interest was a real geographer, though he ranked in the university as professor of geology. Having introduced the geographic viewpoint into his teaching as a member of the Harvard Geological Department, and working in the midst of the inspiring influence of his geographic colleague Shaler, Davis has developed an American school of physical geography whose influence has spread throughout the whole field of American education. A generation of physiographers has been reared by the genius and tireless energy of Davis, and, as in the case of Agassiz in natural history, the extent of the influence of the master has been broadened by the work of his pupils and by others less recognizably under his direct influence.

But this peculiar manner in which geography has found a place in the American university has resulted in its occupying a rather anomalous and somewhat narrow position in the curriculum. Ordinarily geography is merely a part of the course offered by the geological department, and the teacher of it may rank as professor of geology, as in fact is the case with Professor Davis himself, who is not professor of geography in Harvard, but Sturgis Hooper Professor of Geology. In some of the better universities and colleges no provision whatsoever is made for any geography excepting such elementary instruction in physical geography as a professor of geology can give in addition to his purely geological teaching. In such cases there is little basis or opportunity for geographic research. A still larger number of the leading universities have one or more men who give their entire attention to geographic subjects in teaching and research; and a few make special provision for other phases of geography than physical geography. Yet, with but few exceptions, this geographic work is offered in the geological department, or in the department of "geology and geography." In a very few cases geography stands as an independent department coordinate with geology, from which it has in most instances been recently divorced.

The evolution of geographic instruction in the American university, in the main on the basis of previous university recognition of geology, has been extraordinarily rapid in the last ten or fifteen years, during which most of it has taken place. Whether similar development will continue for another decade cannot be told; but it is clearly evident that geography has at last gained a position in the American university curriculum from which there can be no recession. Three or four of

the larger universities have set an example of broad policy, recognizing geography fully and providing for the teaching of a number of its important phases, as in Germany. Others, also among the leading universities, have scarcely taken the first step, but it is to be confidently expected that these laggards will not long remain so far behind. The example so long ago set by Germany, and now fully adopted by a few of the more progressive American universities, may fairly be considered the goal toward which the best of our universities will tend.

It is to be noted, however, that scientific geography in the American university is at a disadvantage as compared to its position in Germany. It is not to be expected that university trustees will provide teachers in subjects not demanded by students, nor can they properly make much further provision for the expansion of elementary instruction. To the German university there come students with previous good training in geography, much of it on a par with some of our elementary university geography. There is also a body of earnest students who in their desire to master special subjects correspond more nearly with our small group of graduate students than with our overwhelming numbers of undergraduates. These students are not content with mere elementary work, even though their main interest lies in history or in botany. The point to be noted here is that the teacher of geography in the American university may be obliged to justify his appointment more in elementary courses than in advanced study, — and an examination of some of the courses offered seems to indicate that this is the real condition. If so, we may not hope for the great scientific result in America that recognition of geography in the university has brought in Germany.

Finally, there is the difference in the utilitarian influence in Germany and in the United States. There a demand exists for men and women trained in geography before they are allowed to teach geography. Here pedagogy is not commonly placed ahead of knowledge. The principle that "a person can teach anything if only he is a natural teacher" finds far less encouragement in Germany than in America. Only in our larger cities, and in not all of these, is knowledge ranked with pedagogical power. Moreover, almost equally with England, geography as a school subject is neglected in the United States. A student in his most immature period has a few years of geography study, then comes an intermission, then perhaps a course in physical geography or commercial geography, or possibly no geography at all. The high school geography may be given to almost any one, very likely to the least burdened teacher, possibly of drawing, or Latin, or English. For those who plan to be teachers there is little need of studying uni-

versity geography. This contrasts strikingly with Germany, where there is a well devised course of geography in the schools, and where a geography teacher is supposed to know geography.

The condition in America undoubtedly has had, and still has, a very important influence in retarding the development of geography teaching in our universities. It will continue to be a disadvantage as compared with the conditions in Germany, but there is another phase which is hopeful. With the development of geography in the university curriculum there will doubtless spread an influence down through the grades as a result of which the teaching of the subject will be both extended and improved. Perhaps one of the greatest reasons for the weakness of our school geography is the fact that the subject has not hitherto found adequate recognition in the American university.

R S T.

**University Courses** — In Germany the offerings in geography vary with each semester. For example, there were in the winter semester of 1910-1911 seven courses at Berlin, one at Halle (on Arabian geographies), one at Heidelberg, five at Leipzig.

In the English universities the advance in the study of geography has been due in the main to the development of commercial courses in the newer institutions. At Oxford a School of Geography was established in 1899 with the aid of the Royal Geographical Society, and has a faculty consisting of the University Professor in Geography, an assistant, and lecturers in ancient geography, and the history of geography, an instructor in surveying, and a demonstrator in geography. Diplomas and certificates are awarded in the subject. At Cambridge a Board of Geographical Studies, working in conjunction with the Royal Geographical Society, exists to promote geographical research and study and to arrange courses. There are a University Reader and lecturers in geography. The subject may be offered for the ordinary B.A. degree, the examination covering physical, historical and political, economic and commercial geography, cartography, history of discovery, and elements of ethnology. Diplomas are also awarded by the Board of Geographical Studies. At the University of Manchester courses are given in the faculty of arts by the lecturer in geography, in the scope and meaning of geography, in geography of a special area, political and economic geography, and a practical course and a seminar are conducted, while physical geography is given in the faculty of science together with geology. At the University of Liverpool courses are given by two lecturers in classical geography, general principles, physiography, commercial, historical, and regional geography.

The development of the subject in America has already been dealt with. Here a few

courses and number of instructors in the subject will be given from a few representative universities.

*Harvard* — Professor, assistant professor, and an assistant. For undergraduates Physical Geography — lectures, laboratory work, and field excursions. For graduates and undergraduates Physiography of the United States, Geographic Influences in North America, Physiography of Europe, Geomorphology, Geography of South America, and (for graduates primarily) a research course in Physiography.

*Yale* — Professor and two assistant professors. Undergraduates Physical and Commercial Geography followed by environmental influences on man's activities, Anthropography, Physiography. Graduates Physical Geography, Geography of North America, South America, and Asia.

*University of California* — Three assistant professors and one instructor. Lower Division General physical geography, Introduction to Economic geography, the materials of commerce, Introductory geography, Physiography of the lands, Topography maps and models, Relief modeling, Elementary meteorology, Geography of Spanish America, Historical geography (two courses). Upper Division Historical geography of Modern Europe, Economic geography of the United States, General climatology, Oceanography, California map, Geography of North America, Geographical influences in the Western United States, Climatology of the Pacific Coast, Glacial geography, Geography of California, Geography of Africa. Graduate Courses Physiography of the Pacific Coast, the teaching of physical geography, Special studies in physiography and climate, Commercial resources of the Spanish-American Countries.

*Chicago* — Professor, two associate professors, and an assistant. Undergraduate Commercial geography, Economic geography, Climatology, Influence of Geography on American history, Political geography, Climate and man, Economic geography of North America, Economic geography of Europe. Senior and Graduate Commercial geography, Economic geography of tropical countries, Principles of geography, the geographic problems of the Orient, Cartography and graphics, the historical geography of American cities, the natural resources of the United States, their exploitation and conservation, some principles of Anthropogeography, geographic influences in the history of New England, of the Interior, of the Middle Atlantic States, History of Geography, Research courses. Courses in physical geography are given in the Department of Geology.

*University of Wisconsin* — Given in the Department of Geology. Undergraduate Short course in geography, Physiography and geography, Physical geography for commerce students, Economic geography, Regional geography.

*University of Pennsylvania* — Given in the Department of Economics. Undergraduate Political geography, Economic climatology, Geography of Europe.

### Geography in the Schools — United States.

— Geography has long held an important place in school work in the United States, both in elementary and in secondary schools. Geography has at times been considered by some to be the fundamental subject in elementary schools, about which all other subjects must center (see CONCENTRATION; PARKER, FRANCIS), by others, geography has been and still is considered a catch-all subject which has little inherent strength of its own, but yet must be given some place. By others, and the number is constantly increasing, geography is held to be one of the fundamental subjects of the curriculum, tested as to its worth and capable of being developed by good teaching into one of the most significant of school subjects. Geography as the study of the earth in its relation to man deals with elements of the environment of deep significance to all, and is of great value because of the aid it gives to other subjects in the curriculum.

Geography is no longer generally considered merely an informational subject which permits some attention to necessary, detailed facts to be known by all. Although facts are vital and necessary in the subject, geography, as a

study of relations between the physical environment and life in a causal way, is decidedly a study of principles of great working significance. Geography, rightly taught, imparts to the pupils a knowledge of large relations over the world, which all must know to understand current events, world-movements of people, or the problems of commerce of to-day. Geography teaching, therefore, has for its purposes the imparting of a working knowledge of the principles of geography and training in working with geographic relationships and geographic materials that gives pupils a power to use their knowledge in later life. This viewpoint is fundamental and vital in both elementary and secondary school geography, but as yet secondary school geography is so specialized that these larger purposes are often lost sight of in the endeavor to give training in specialized, scientific thinking in a narrow phase of geography.

**Elementary School Geography** — The character of school courses in geography is now, as it always has been, largely determined by the content of the textbooks in use. In the earlier part of the last century, the school texts were topical in order and were planned to cover the geography of the world in a brief way. Later, the geography course was represented by two books, an elementary and an advanced, or a first and second book, and that plan holds to-day. The plan of the earlier book was to present the larger, more general items of geographic interest, to be followed in the larger book by a more broad consideration of the same topics. These books dealt largely with the facts of political and of physical geography and gave little attention to geographical relationships.

The first departure from the earlier plan was in the Guyot Geographies of 1866, in which emphasis was given to human relations to physical conditions, and in which maps were made of vital significance. Guyot's books were, however, ahead of their time, and the principles of Guyot, now recognized as of great significance, were but little developed by others. (See GUYOT.)

The first great change from the plan of these earlier books was in 1894, following the *Report of the Committee of Ten* (qv) of the National Educational Association. Owing to a renewed interest in physical geography, and to a recognition of the importance of observational work in geography, much emphasis was given to physical geography in all phases of school work. The first geographies which appeared after this *Report* gave a new impetus to school geography and introduced an era of progress of great significance. Although these early books placed great emphasis on physical geography, they did not ignore the life side. The new ideas were grafted on to the old without supplanting it to any great extent. They proved the importance of thought work as

against memory work in geography, and since that time the endeavor has constantly been to make geography more real, more vital, and more thought-provoking to pupils.

The recognition of the well-founded educational principle that pupils' work must be based on previous knowledge in all fields of study, has led in the last decade to the inclusion of home geography as the fundamental phase of school geography work. Home geography is planned to help children in organizing their everyday experiences and to see the simpler relationships of life to its physical environment illustrated in every locality. Simple generalizations, based on these local studies, lay a foundation for extending the children's work so as to include the world whole, which forms generally the second stage in school geography work. The development of the simpler ideas of the world as a globe, and of the distribution of the continents over the world, gives a background for the earlier study of certain of the continents and countries of the world, through maps, pictures, and text. Usually these earlier phases of geography are followed through the fourth, fifth, and a part of the sixth year of school life, up to the time when many pupils leave school.

In the later years the continents, or certain of them, are again studied from a somewhat different standpoint through the sixth and seventh years. This advanced continental work, in which much attention is given to commercial geography, is usually preceded by a study of certain of the principles of mathematical and physical geography, to lay a foundation for a careful causal continental study. In other cases, this work is placed as the climax of the course as a specialized phase of geography. In a few instances, geography, as an all-round subject, is closed in the sixth year. The geography of the later years is very specialized and is devoted to the commercial and industrial aspects.

In by far the greater number of large cities in the country, geography is taught from the fourth to the seventh years inclusive, though there is an increasing tendency to restrict geography work to three or to three and a half years. By far the larger proportion of the time devoted to the subject is given to the study of the regions of the world, since political geography, as it is often called, forms the larger phase of geography that pupils come in contact with in after life. This regional work naturally includes the study of physical and commercial conditions as well as of political conditions, and involves much study and training in the use of maps as well as of text and supplementary materials. Such a course of study is generally followed throughout the country, according to the plan of the texts in use. In an increasing number of places the course of study is now specially planned to meet local needs, and hence the

order of treatment of topics and phases of the subject may vary extensively. In by far too many localities, however, the text forms the only course of study used and the yearly programs are measured in pages of the text.

There has been great progress in school geography teaching in the last few years. Better texts, better maps, better trained teachers, improved training courses in normal schools and some colleges, and a larger supply of valuable and accurate supplementary volumes have all contributed to the improvement of the subject. The greatest weakness in the field at the present time is a lack of first-class wall maps and a dearth of reasonable-priced, accurate school atlases. In these mechanical attributes of good geography teaching, the United States is far in the rear as compared with Germany, France, the United Kingdom, or even with a small country like Switzerland.

The history of the development of elementary school geography in this country has shown that progress has always been made through evolution and not by revolutions in content or plan. It is not likely that the general content of elementary school work in geography, the outgrowth of generations of experience, will be overturned in the future. As old subjects are tested by modern scientific methods and found wanting, they will be replaced by more rational and vital topics. Much progress has been made in eliminating from school work topics in geography that are not pertinent to the needs of pupils, and which are too adult for school use. A conservative public will, however, permit such changes to be made only slowly, while the demand that all that is new and perhaps of little value should be included, is widespread and insistent. The great problem for the future is the judicious modification of the course under the expert guidance of trained and interested geographers and leaders in modern education.

**Secondary School Geography** — Secondary school geography in general falls into three categories, according to whether the work is presented in the earlier or later years of the course. Physical geography is the favored phase of geography in secondary schools and receives the greatest attention in the first or second year of the course. In many schools, particularly those preparing pupils for college entrance examinations, an advanced type of physical geography or physiography, as it is often termed, has a place in the later years of the course. Until within recent years, physical geography has been given a place in secondary schools because of its informational value, and its content was determined from that standpoint. As thus presented, it had no unity and little value as a science. The development of physical geography by American workers in field and classroom has shown the subject to be rich and full as a cultural and scientific study. In consequence, the pendulum has

swung away from the older informational subject toward a newer, rationally organized physical geography

It is now generally recognized that enthusiasm for the newer point of view has carried us to extremes, and that physical geography as such has received an undue proportion of the time that can be given to earth science in secondary schools. If the task of the secondary school is to prepare pupils for after-school life, then obviously the content of geography and other subjects must to some extent be determined by the conditions in the adult world. In these modern days, pupils are going to be confronted in the business world with commercial conditions, and through the press they will constantly be brought in touch with the general geographic conditions of the great nations of the world. The development of modern commerce has, since about 1900, caused an ever increasing attention to be devoted to commercial geography in secondary schools. As a rule, this needed phase of the work has been organized with little attention to its relations to physical geography. Like the latter work, commercial geography is found prominent in both the earlier and later years of the course. The rapid development of commercial geography is indicated by the fact that, while but one book was available for secondary use in 1901, at least ten much-used books exist in 1911.

Commercial and physical geography are so closely related in a causal way that neither can well exist independently in a course of study. Hence the demand has arisen that these phases of the work be coordinated more closely in secondary schools. Two committees, one from the National Education Association in 1909, and the other from the Association of American Geographers in 1910, recommended that the one year to be devoted to geography in secondary schools be divided so that one half the time be given to the essentials of physical geography and one half to commercial and regional geography. This latter recommendation is based on the conviction that pupils ought to study the general geography of the United States and Europe, at least, in the high school, as a contribution to their general training and as a basis for efficient work in history, economics, botany, zoology, and other subjects that deal with facts of distribution. Physical geography as a college entrance subject has never held an important place in secondary schools, and is particularly developed in large public schools or in private secondary schools where funds are available for securing the necessarily inclusive and somewhat expensive laboratory equipment.

*England.*—School geography in England has progressed rapidly in the last few years; though in many ways it is still very unsatisfactory, as it is in America. The modern development of interest in geography, particu-

larly in the higher schools, dates from 1886, when the classic report on geographic instruction was published by the Royal Geographical Society from the pen of Dr J. Scott Keltie, who made a thorough and painstaking study of geography teaching in England and on the continent. In general, the plan of work advocated for the elementary schools of England is similar to that in America, though greater emphasis is given to physical geography in the several standards. The plan of beginning with local, observational geography and working out to the geography of the world, with a special study of selected countries in later years, is followed. A large number of improved textbooks and books on teaching makes effective work possible, and the work of the Geographical Association has done much to arouse teachers to a realization of the possibilities of geography.

In the secondary years much more attention is given to regional geography than in America, and physical geography, as such, has a distinctly subordinate place. The work is, therefore, well coordinated and definite, though its content is largely determined by the examinations set by the larger universities. The outlines in present use show great advances over those of 1885-1886, and indicate how far-reaching in its influence has been the establishment of geography as a university subject in the larger universities and colleges. Inspiration and guidance have come from the leaders in the higher fields of geography teaching and have caused a very significant revival of interest in school geography. Furthermore, the leading business men have realized that England as a commercial nation must give more attention to geography teaching in the schools.

*France.*—Geography in the schools of France runs in cycles, the climax of the two cycles being a study of France and its colonies. Beginners are led through an observational study of the local environment outward to the world whole. This is followed by a study of the continents, and is brought to a summary in the fourth school year in a study of France and its colonies. In the second cycle, which is completed in the eighth school year, the elements of physical geography are followed by a study of America, Australia, Asia, Africa, Europe, and again is brought to a climax in a more advanced treatment of France. This work is largely presented through excellent textbooks which order the content of the course in a definite way. In the secondary school the same idea of cycle is followed. In the first year the history of geography, physical geography, political and commercial geography, and a brief course in geology constitute the outline of work. This is followed in the second year by a special study of France in great detail, and the outlines of cosmography. The character of the geography work in the later years is determined by the special course

of study followed by the pupils and is in no case complete or closely related to the earlier work. Thus geography teaching in the elementary and secondary schools of France is very largely political and regional geography, so arranged that pupils will, as the years pass, become increasingly familiar with the geography of their own country and its economic, political, and physical features.

*Germany* — Probably in no country in the world is geography in schools so well organized and taught as in Germany. Teachers are trained for their work, and the supply of available books, atlases, and maps is without a parallel for quality, accuracy, and usefulness. Excursions have been developed generally as an important phase of school work, and geography is thus a matter of things and not of words or imaginary pictures, as is so frequently the case in America. The general order of the divisions of the course is similar to that in America. Following a study of the home surroundings by observation and of Germany comes a brief treatment of the several continents of the world. This is in turn followed by a study of the continents from the physical standpoint, in the years corresponding to our upper grammar grades. The climax of the work is a course in general geography with special emphasis on physical geography, and of political and commercial geography. As in America, greater emphasis is, in recent years, laid on commercial geography from a broad viewpoint. This plan, roughly outlined, differs little in general plan from that of many years ago. Progress is indicated by change of emphasis of details, rather than in any variation in the larger steps of the course. A pupil who completes the nine years of prescribed work in geography has a good knowledge of elementary geography in all its branches and has learned how to use his knowledge in the specialized later school work, with great profit to himself.

**Methods of Teaching Geography** — Until within a few years geography teaching in American schools, both elementary and secondary, largely followed one method, — the pupils memorized the words of the textbook without, as a rule, any adequate comprehension of the meaning and significance of the material studied. Where maps were involved, these were studied in the same way. Pupils were encouraged to search maps to find obscure and well-known places, with no thought of giving them any training in the use of latitudes and longitudes. Thus they gained no assistance through the exercises that would have helped them to find other places by the same method. In recent years the character of geography teaching, in both elementary and secondary schools, has radically changed, although the old memoriter method still persists in many school systems where the teachers are not trained in modern methods or are out of sympathy with their tasks.

As the former method was characterized by memorizing, the new method is characterized by reasoning. The reasons for geographical facts are studied with the facts and through the facts, and the "casual notion," as it has been so aptly named, is the keynote of geography work. In this study of the relations between human geographic conditions and the underlying physical conditions, much use is made of maps, not merely as sources of information, but as valuable media for depicting geographic features of all kinds. Map hunting has given way largely to map reading, and pupils are taught to use a map as they would their texts, as one of the most valuable bases for study. In the specialized work in secondary schools, great emphasis is given to the map study of land forms, ocean conditions, climatic conditions, and to life geography. The new point of view in reference to geography work, and the realization that ability to work with geographical materials is of greater value than mere information, together with the recognition of the importance of making facts and principles real, has led to the introduction of laboratory work, particularly in secondary school geography. In some cases laboratory work merely consists of the desultory study of graphically presented facts, because the curriculum calls for laboratory work. Under these circumstances laboratory work is often an irrational phase of geography teaching, of little more real educational value than the busy work of the primary grades. In the better schools laboratory work, however, is a vital part of the study and is made the foundation in the first presentation of most new topics. The influence of laboratory work, which calls for the study of things and the graphic representation of things, has had a large effect upon the method of study in elementary schools, where observation of local phenomena, the study of land features, human relations, and industrial conditions, through excursions, together with the study of weather records and similar work in other fields, have become a vital supplement to map and text study.

*Methods in Elementary Schools* — There are many different methods in vogue in elementary schools, either for portions of the course or for the course as a whole. In general, the best method is that which permits the individual teacher to make the best use of his personal powers in securing the progressive advancement of his pupils with the least waste of effort on their part. A skillful teacher makes use of many methods in various stages of the work and does not attempt to organize the course of study about some one plan of procedure. Among the various methods that are used sufficiently to be named, are the observational method, the journey method, the type method, the map-drawing method, the topical method, and the inductive method. Masters of each of these several plans of procedure can

avoid the dangers and develop the strong features of their plans so that the progress of the pupils is secured, but mere followers of a plan, with perhaps little reserve knowledge and a narrow viewpoint, easily become the slaves rather than the masters of the method, and the pupils become the unfortunate victims of misguided enthusiasm.

The *observational method*, the study of things, obviously ought to be followed in school geography teaching at every opportunity, especially in the home geography work of the earlier grades and in the study of the atmosphere, land forms, and local industries. Modern education requires that all subjects be made real to pupils, and in no subject is this need greater than in geography. By emphasizing similarities or contrasts with local features, distant geographic conditions may be made real. This requires observational work at all times.

The *journey method*, whereby countries or portions of a country are studied in the order in which they would be seen in an imaginary journey, is obviously valuable at certain stages. Further, this plan of procedure is interesting to many imaginative children and permits the ready use of supplementary materials. The journey method followed blindly, however, does not readily permit the teaching of a country as a whole and the emphasizing of causal relations. This method, therefore, seems better adapted to the earlier than the later grades of a school course. Such a method of procedure causes knowledge to be related to steamship routes and railway lines, and not to be centered about political areas, as is generally necessary and advisable. It has a special value in the early study of the world whole, and to a certain extent in the later work with the commercial side of school geography.

The *type method* is found in use in various phases in American school geography work. According to this method, one section or area is studied very fully as a basis for comparison; and other areas, similar to the selected type, are passed over quickly. If the selected area is a political and physical unit, a lengthy study of the section may result in an over-emphasis of minutiae, so that the area does not stand out in the pupil's mind for its salient features. If the selected unit area is a section about which some human interest centers, and is not a political or physical unit in itself, it fails to be a geographic unit and hence is a poor basis for comparison. One weakness in the teaching by such types is that political areas are studied incidentally and perhaps are not clearly understood. Yet political areas are foundational in any use that is made of regional geography in everyday life. The great advantage of the type area is that it permits a careful study to be made of a few sections, so that pupils may get a real comprehension of the value of geography and so

that it provokes natural reviews. The latter fact is the strongest argument for following the type method in certain sections of school work.

The *map-drawing method* is now but little used, though a generation ago it was much in vogue. Pupils, by this method, are taught to draw maps by a rule of thumb plan and are trained to visualize their products. For pupils who have a good power of visualization, this method has its value, provided the maps are drawn according to an understandable scale and on a projection that does not too much distort areas.

The *inductive method* has never been much employed in American schools, for the obvious reason that geography deals with many facts beyond the students' experience, and a real comprehension of these impersonal materials can be more readily imparted by a plan that consumes less time.

The *topical method* is generally followed in the upper grammar grades, though the title covers multitudes of sins, in places. The best use of the topical method is found in the later years of school life, when a causal order from causes to consequences can be followed so as to give training in right methods of working and thinking. The topical method in the lower grades generally leads to the blind memorizing of items of information and not to the development of pupils' powers of work.

As a matter of fact, the method followed should vary with the character of the topics under consideration, with the age and abilities of the pupils, and according to the training of the teacher. Pupils in the early years are interested in the life about them and should in general work out in a causal order from the human and life conditions to the underlying physical influences; in the upper grades, the causal order should in general be followed from causes to consequences. Any teacher, however, who at any time finds himself getting into a rut through too slavishly following one plan of procedure, should, for the sake of himself, his subject, and his pupils, at once vary the monotony by changing his method so as to arouse his pupils into activity.

In all school geography work the danger is that the subject will be presented in so fragmentary a way that all the life is taken out of it. The picturesque side of geography should not be neglected, although it should be subordinated to a well-considered plan of procedure. This side can be brought out best through a rational use of pictures, specimens, and supplementary reading. Obviously, the excursion should be an important part of school geography work in this country, as it long has been in many European countries. Public opinion must be trained, however, to the appreciation of the value of excursions, before they can be generally used in large school systems. School excursions (*q.v.*) are

harder to conduct than class recitations, and, unless in the hands of a wise teacher, degenerate into picnics and are of little value.

One important phase of geography teaching deserves emphasis because it runs all through the grades and has been too much neglected in recent years; that is, training in location. Location is essential in geography, but it does not make up the whole subject, as was so largely the case in the days of "sailor geography," with its lists of capes and capitals. Places and features to be studied as to their location may be divided into three classes, which will be found a good working guide to all teachers. The first class would include those names which should be at the ready service of any intelligent person, class two would include those names which ought to be familiar to all through their school work, so that they can be readily found on a map, class three would include those names which are locally significant, but which are not of equal importance in other regions. By judging any name according to its relative importance, according to this grouping, any teacher may readily work out for himself his minimum of location which he will develop in his class.

*Methods in Secondary Schools* — Modern methods in secondary school geography are characterized by an emphasis on laboratory work. In many of the larger public high schools of the country, specially arranged laboratories have been constructed and equipped with extensive collections of maps, models, diagrams, lantern slides, illustrations, and, in some cases, with specially devised apparatus for experimental work in the development of land forms. In schools where the commercial or industrial phase of geography is emphasized, collections showing industrial products and processes have proved most valuable equipment. The laboratory presentation of topics is sometimes preliminary to the textbook and class study, in the larger number of schools, where the program is rigid, the laboratory work is supplementary to the text and class work. This relation ought to vary with the subject under discussion, for obviously some topics cannot be presented half by laboratory methods and half by classroom methods, as would be implied where the subject has two class hours and a double laboratory period a week. Certain topics in geography, as the study of weather, climate, and land forms, can be more readily approached from the laboratory side than can topics dealing with the ocean or the distribution of plants and animals.

Laboratory work may be introductory to topics and consist of well thought out problems presented in some graphic form, or it may be illustrative so as to give definiteness to the class and text work. The excellent supply of maps from the Weather Bureau and the United States Geological Survey makes this work in certain subjects much more feasible

than it was a few years ago. The lack of good laboratory materials in certain of the other fields has meant, in many cases, an over-emphasis of the land features, so that, from text and laboratory, pupils have secured a warped point of view as to the relative value of the several phases of physical geography. Newer methods, better laboratory manuals, wider conceptions of the right content of geography in secondary schools, have all contributed toward the improvement of laboratory work. It is now conceded that laboratory work is supplementary to class and text work, and not coequal in importance at all stages of progress.

In some schools, where the conditions are favorable, field work is carried on for a few weeks during the year, but field work has not developed to the extent that was hoped, owing to the difficulties incident to field trips. Field exercises may roughly be classed in two groups. In the early part of the course pupils may profitably be taken afield for "field sight," — that is, to get a comprehensive view of a landscape, see its parts, the problems it presents in a physiographic and geographic way. Such field exercises form the basis for class and laboratory work in the closed season of winter. In the open spring season the field exercises may be really "field work," where pupils work out simple problems which have been previously approached through the laboratory and text. As yet, however, excursions have not won for themselves a place in either elementary or secondary school geography, and are little used except in the study of industrial geography through visits to manufacturing and distributing plant. (See EXCURSIONS, SCHOOL.)

**Equipment for Teaching** — It goes without saying that in all geography teaching a good textbook is essential. More than one should be used, if possible. The market is now well supplied with good texts for most of the work of elementary and secondary schools. Laboratory guides, supplemental volumes for reference work, encyclopedias, and books of reference are adequate. The great lack is good wall maps, school atlases, and ample illustrative apparatus for elementary schools. The available equipment for secondary work is in some cases overrich, so that teachers have difficulty in selecting that which is most pertinent.

In elementary schools atlases are practically unknown, and wall maps are little seen and less used. Yet wall maps are of fundamental importance in school work. Every classroom above the third grade in elementary schools ought to have as a minimum map equipment a good Mercator map of the world, a political map of the United States, and maps of the continents to be studied in the respective grades. In the upper grades there should also be physical maps of the United States and Europe and political maps of all the continents, not only for use in geography, but in history,

literature, and current events Yet this minimum is rarely found except in the best schools in our larger city systems Outline maps are also a most valuable adjunct to class work and are now available in cheap and reliable form Pictures, lantern slides, stereographs, specimens illustrating products and industries, models, and government publications, in great variety, are now easily procurable They form most valuable aids to geography study and should be used wherever possible, provided they are selected with care and are used, not for purposes of amusing or merely illustrating points, but as really definite parts of class work from which valuable lessons may be drawn in a clear-cut and illuminating way

Many other valuable forms of equipment might be cited, but a small equipment chosen according to a well-ordered plan and used carefully and systematically is better than a mass of unrelated material used just because it is available The problem of how to use illustrative material profitably is more difficult than how to secure it

#### GEOLOGY — Relationship to other fields

— Perhaps no science shares its field with other sciences to a greater degree than geology As the science of the earth, it treats in its own special way subject matter that falls also to one or another of nearly all the sciences for treatment in their special ways Obviously in its function as the history of the earth it becomes the province of geology to treat the collective results of innumerable agencies and processes that enter individually into the fields of other sciences.

If a survey of the whole field of science be taken to bring further into view the genetic relations of the several subjects of study, it will be seen that the history of the realm from which springs the realistic phase of education discloses two coordinate lines of evolution, each of which embraces a series of progressive steps The one series includes (a) the cooperation of chemical and physical agents in the formation of minute integers leading up to molecules; (b) the combination of molecules in the formation of crystalloidal, colloidal, and amorphous aggregates, (c) the assembling of these into the lithosphere, the hydrosphere, and the atmosphere; (d) the coordination of these in the

formation of the completed planet; (e) the correlation of this with kindred bodies into the solar system, and finally (f) the assembling of solar systems into the stellar galaxy. The other series embraces (a) the cooperation of organic agencies in forming and actuating individualized plasms; (b) the union or differentiation of these in the formation of more complex living organisms, (c) the development of a system of transmittal of organic acquisitions, (d) the initiation of reflex and sense action, (e) the development of a system of registry of sense experiences; (f) the development of sense action and mental registry into higher and higher derivatives, until finally (g) they merge into the declared forms of mental, moral, and social phenomena; in other words, into the very working ground of education itself. The word "finally" is intended here to mean only the last stage of human vision, not at all the ultimate in any sense. These two series run closely parallel to one another and are interdependent. They in themselves imply better than a long discussion the relations of earth studies to other studies. To the student of earth history in particular, the genetic connections of the two series are themselves the best expressions of the vital relations of the sciences and serve as the most reliable guide in interpreting and evaluating their educational functions. The natural paths for educational procedure, so far at least as genetic considerations have weight, lie up and down the historical lines, for these disclose the real places that have been taken by the participant factors in the natural order of things. In the details of a formal study there is a choice between starting with the more primitive and the more undifferentiated and thence working toward the more segregated and the more individual, and as an alternative, starting with the last stages, the end products for the time being, and working backwards along the lines of genesis toward the more primitive and the more undifferentiated, but in natural practice — with little doubt the best practice — both courses have been followed interchangeably and often in such close succession as to make the method a type of reversible mental action, an almost spontaneous gliding from antecedent to consequent and immediately back from consequent to antecedent, from parent to offspring and at once back from offspring to parent, and so up and down from one link of the genetic chain to another in either direction, as occasion offers.

It is of course fully recognized that when the historical or genetic factor has little instructional value, which is perhaps only true when it is unimportant to know how the subject or the state under study grows out of or grows into other subjects or other states, the educational process may play more freely to and fro across the lines of natural sequence or in neglect of them. It is of course recognized

that underlying the whole web and woof of antecedents and consequents there are many factors common to several or to all lines of succession and these may be treated to advantage independently, artificially, or "abstractly" and precedence given to their own kinships of qualities rather than their genetic or historical relationships. This mode and the genetic mode are complementary and coordinate, not antagonistic or even competitive.

**The Essential Factors of Earth Study** — The study of our dwelling place involves four main factors: (1) the study of the birth of the earth; (2) the study of its structure and composition, *i.e.* the earth's mechanism, (3) the study of the energies, organic as well as inorganic, that actuate it and the modes of their action, *i.e.* its processes and its dynamics, and (4) the successive interplay of these, *i.e.* its history. From the higher point of view of earth science neither of these factors by itself can yield the highest educational results, for neither leads the mind to all the essentials of a round view. In world study at least it is not enough to know the origin or the mechanism alone, nor the processes and energies alone, there must be a study of the actual workings and, for a rounded, guarded, balanced view, a study of the long chain of blended processes and results actually realized in history.

**Historical** — *The Primitive Stages of Earth Study* — In the primitive education of the various peoples, the crude products of earth study, if study it may be called, had a rather large place in the small total of educational agencies that took part in guiding the primitive ways of life. Such information as was picked up and handed down related chiefly to the immediate needs of life and may be said to have been forced by daily requirements rather than sought for the love of knowing. The additions that were slowly made as time went on more largely took the form of a widening of imperfect knowledge than of a careful sifting of what had been acquired. It is true that then as at all times testing by trial sifted, in some measure, what passed for knowledge, but it was incidental rather than purposeful, and the critical spirit of science was not yet born. The whole was very crude, yet it was very necessary. The primitive school of earth lore was the open school of life's necessities. It was indeed so broad that it was shared by many of the higher animals, each in its own peculiar way, and some of the attainments of these animals in the line of keen geographic sense and acute knowledge of local topography compel admiration.

The earth lore of the human race in these early stages was chiefly of the geographic rather than geologic type. (See GEOGRAPHY.) There was, however, some rude beginning of acquiring knowledge relative to crustal structure and composition. Caverns were explored and occupied, structural material was chosen

and built into shelters and homes, stone was selected and fashioned into weapons and tools, certain ores were discovered and smelted, and the use of metals begun. A crude form of economic geology was thus slowly brought into being and took part in the rude training of the primitive races. There can be no doubt, also, that even the rudest peoples were impressed by earthquakes and volcanoes, by floods and landslides, and more or less by the gentler geological processes, but these impressions seem to have tended rather to weave themselves into fantastic conceptions than into sober inductions of the scientific order. While these beginnings of geologic knowledge can scarcely be classed as science, they cannot be disregarded as elements in the primitive education, for they were in reality germinal. At these early stages there does not seem to have been more than vague imaginings of what the earth as a whole might be, and such speculations as were indulged in respecting its origin were of the mythical anthropic order.

Throughout this primitive stage no other concept than that of a flat earth appears to have had any vogue; and so the belief that the earth was essentially a plain may be taken as the most tangible criterion to set off the primitive stage from the more advanced stage that followed it. It seems strange, and yet is perhaps not so strange as it seems, that the geographic dispersion of the race should have well-nigh wrapped the earth about, while yet the notion that it was flat prevailed. Even within historic times and among the Mediterranean nations of much lauded intellectual attainments it was regarded as a great step toward unity and completeness to be able to map the land as a circular or elliptical plain, girt about by the great river, Oceanus.

*The Stage of Speculative Extension* — When the epoch of the flat earth, the earth of common vision, began to give place to the spheroidal earth, the earth of corrected vision and of scientific imagination, the unscientific imagination came also into play and a whole troop of visionary conceptions of modes of formation sprang into being. There was at first little restraint from chemical, physical, and astronomical knowledge, or from scientific training, and so fantastic speculation ran riot for a time. In this the pre-Grecian peoples indulged freely, while the idealistic trend of the Greek mind lent itself peculiarly to this indulgence. A long line of eminent Greeks drew in turn a varied series of pictures of earth genesis among which the metaphysical were dominant; but still these were stimulative and clustered about some substantial seeds of truth. As early as the sixth century B.C. Anaximander, doubtless working on germinal ideas derived from Thales, set forth his conception of a fluidal evolution of the earth and of the stars. He conceived the earth to be round, and set it in the center of the universe. Mystical as his

view was in most respects, it recognized physical stages in cosmic development and was the germ of a new order of thought. In the same century Xenophanes noted the remains of mollusks and of plants imbedded in rocks and took a step toward fossil biology. This was scarcely a step in paleontology, even in embryonic paleontology, for Xenophanes seems to have had no thought of a series of ancient types leading up to the present types and making up a biologic genealogy. He merely recognized the burial of existing types of life during a previous incursion of the sea. Xanthus, a century later, and Herodotus, still later, recorded other cases of fossil remains and strengthened the theory of former inundations. Empedocles, in the fifth century, studied Etna and noted other signs of internal heat and became the father of all such as believe in a molten interior.

The doctrine of a round earth grew into the creed of a school when the Pythagoreans adopting it gave it a congenial metaphysical basis and made it popular with the Greeks. The sphere is the most perfect of forms, it is therefore the fittest form for the home of man, hence it is the form of the home of man. The Sophists and the Platonists as they came into influence still further pushed into ascendancy the dialectic and imaginative tendencies in earth study, and the scientific mode of proceeding by successive tests, never as yet more than feeble, was overwhelmed. There was some little recovery under the leadership of Aristotle, who combined in a singular way the speculative and the empirical methods. He recognized stages of earth development and some other vital features, but there was little of the spirit or method of modern geology in his treatment of the earth. Theophrastus wrote on minerals, stones, and fossils, and something approaching a text in geological lines began to become available.

A contribution of the genuine scientific type came out of Egypt when, near the middle of the third century B.C., Eratosthenes measured a degree and thus laid the basis for a real estimate of the size of the earth. To this solid contribution he added various hypotheses of the more sober order relative to mountain chains, to the former presence of the ocean above the continents as implied by fossils, to the work of water, and to the phenomena of volcanoes and earthquakes.

The Roman period naturally brought a more realistic spirit and in the course of the wide expansion of the Empire, a larger need for geographic and geologic information. Strabo, Seneca, Pliny the Elder, and Pliny the Younger added largely to the stock of earth knowledge, as well as suggestive interpretations of the more striking of the earth processes. In their treatment of volcanoes, earthquakes, subsidences, and elevations, as well as the work of water, they often touched interpretational

grounds occupied later by the older school of geologists

Marinus of Tyre and Ptolemy of Egypt added much oriental knowledge to the accretions of the Greeks and Romans, and all this material coming later into the hands of the Arabs was partially saved from destruction during the brecciating stages that followed the downfall of Rome, and thus became the possible seeds of a revival of earth study in Europe when it emerged several centuries later from the shadows of the dark ages. In actual fact the revival was probably more largely spontaneous than inherited.

*The Transition to a Truer Basis* — The brecciation of the Roman Empire not only involved the destruction of a large part of the material for education in earth science that had been gathered by the Egyptians, Phœnicians, Greeks, and Romans, but the catastrophe was followed by the rise of a form of scholasticism that came to be a grave obstacle to the resuscitation of earth study on a true basis. The obstacle was not so much a barrier to the regathering of statistical data as a restraint put upon the free interpretation of the processes by which the earth had come to be what it is. To fully appreciate the educational contribution which geology made in rectifying ethical attitudes and intellectual methods, the sterile obstructive nature of the retrocession of the Middle Ages must be duly weighed.

The issue of these ages at first centered on the nature and meaning of fossils, not altogether a new issue, but one revived with new intensity. On the one hand, it was held that the lifelike shapes in the rocks were the products of a *vis plastica*, or of some form of molding force in the earth, or else were a Mephistophelian device for the deception of man; on the other hand, it was urged that they were true relics of former life entrapped in the growing sediments in the natural course of events. It was at bottom an ethical issue, a question as to the integrity and fidelity of the record of creation, if not of the honesty of the creation itself.

Although Xenophanes had recognized the genuineness of fossils in the sixth century B C and had been followed by many others in the classical ages, so great was the retrocession attending the breakup of the Roman Empire and so deep was the neglect into which determinate data had fallen through the establishment of medieval scholasticism, that Leonardo da Vinci in reaffirming the genuineness of fossils was perhaps as much a pioneer in the fifteenth century A D as Xenophanes had been in the sixth century B C and no doubt had greater need of courage. The views of Da Vinci were probably original, at least they were concrete and based on the close and accurate observations of an engineer and an artist. While Da Vinci clearly recognized that fossils implied changes of land and sea and were

marks of former crustal events, it is not clear that he saw in them the record of a succession of different faunas and floras. Besides others, he was followed by Alexander, who had observed fossils in the Calabrian mountains, and notably by Francastorio, who built a strong argument on the fossils of the rocks of Verona.

As soon as the genuineness of fossils had made appreciable headway against the imitators or simulationists, the issue took on a new phase, in which the two parties were those who assigned the fossils to the Noachian deluge and those who held that they recorded a much more ancient history, the diluvialists and the nascent paleontologists. In the belief in a Noachian flood then prevalent there was at once an element of aid and a deterrent. With such a belief, it was not unnatural that fossils should at first be thought to be relics of that flood, and proof of it. Not unnaturally this belief prompted the collection and description of these *diluvii universalis testes* and so added data and broadened interest. At the same time, the belief developed and deeply implanted an erroneous element of interpretation that soon grew to be a formidable barrier to the true view. But with the best minds the very attempt to make the fossils serve as witnesses to the deluge led to observations inconsistent with so recent and so brief an event and turned them toward the true view. Nicolas Steno, in the middle of the seventeenth century, followed a little later by Vallisneri, Moro, and Generelli, gave start to an Italian school working somewhat on modern lines. They are perhaps entitled to be regarded as the pioneers of modern historical geology. In the later part of that century, Robert Hooke of England became the pioneer of an English school of a similar type, and here and there in other parts of Europe there arose centers of like order which spread the leaven of the nascent modern movement, so that by the middle of the eighteenth century the pioneers of the modern school had gained a firm footing. Meanwhile the advocates of mystic simulation or of Mephistophelian purpose had fallen into discredit, but the diluvialists still retained a large and influential following. This school can scarcely be said to have lost a place among contributors to geologic data until the stratigraphic series had been worked out so fully as to leave no question that there had been a long series of successive depositions in which there was imbedded a like succession of faunas, a work which, though much advanced by many workers in the latter part of the eighteenth century, did not become a declared achievement until William Smith of England, Cuvier of France, and others of the early nineteenth century had brought paleontological science into clear definition based on irrefragable evidence. Meanwhile, however, the diluvialists were being gradually replaced by a catastrophic school who assigned the successions of ancient

life to a series of creations following previous general or partial destructions.

While these crucial issues relative to life held the front of the stage, notable advances had been made on the inorganic side resulting in a broader and more specific knowledge of the composition and structure of the rocks. This was in part incidental to the study of the strata and the fossils and in part stimulated by economic considerations, but it arose also in part from a growing desire to know for its own sake. Leonardo da Vinci, Nicolas Steno, and others who had taken leading parts in the organic problem, were large contributors here also. Lehmann, Fuchsel, Arduino, and others assembled and systematized the existing knowledge of minerals, rocks, ores, and structural phenomena, and began tabulations of stratigraphical sequence.

Just at the turn of the century a notable issue arose between those who held that the basal rocks were formed by crystallization from solution in water, the Neptunists, led by Werner, and those who held that they were formed by solidification from the molten state, the Plutonists, led by Hutton. The issue went over into the nineteenth century, opinion drifting toward the Huttonian side.

Concurrent with these special movements on the biological and physical sides, there was also a revival of theoretical effort on somewhat firmer grounds than those that stimulated the Greek speculations. Descartes, Leibnitz, and Buffon gave forth views of the formative stages of the earth, which, though inadequate or erroneous, served to gather the scattered thought of the time into unity, to enlarge the field of view, and to stimulate thought in quarters where the unorganized details failed to awaken interest. These were followed near the close of the century by the speculations of Thomas Wright and Kant and by the definite hypothesis of the Marquis de Laplace that later came to monopolize the term *Nebular Hypothesis*. Thus the latter half of the eighteenth century greatly enriched and gave truer trend to the rather crude rejuvenations of the three previous centuries, and in so doing prepared the way for the more rapid and sounder development of the geologic sciences in the next century.

The nineteenth century was in fact the first round period of really well-organized, wisely directed geologic effort. During the early and middle portions of the century there was a pronounced effort to harmonize the geologic record with the interpretation of the biblical account and with views of creation then widely prevalent. Modified forms of the Laplacian and Kantian hypotheses of genesis came into general acceptance and were woven into these efforts at harmony. The leading dynamical interpretations of the earth were made to conform to the contractional postulates of these hypotheses. The molten earth of Empedocles

was a scarcely questioned tenet and was thought to have a firm basis in the rise of internal temperature, in volcanic phenomena and in the cosmologic hypotheses. The early earth was conceived to have been enshrouded in hot gases of immense volume and density which suffered progressive depletion as time went on. Widespread uniform tropical climates were held to have prevailed in the early ages and to have been followed by more diverse and cooler ones in the later ages. Seasons, aridities, and refrigerations were features of the later periods alone and by forecast were made the forerunners of still more complete atmospheric consumption in the future leading on to a final refrigeration. Geological progress was held to be marked by cataclysms destroying all life, and these to be followed by new creations. It is within the memory of the writer that complete destruction of life at the close of the Paleozoic and of the Mesozoic eras respectively was taught in standard American colleges and by the most authoritative American textbooks. At less important stages partial destructions and corresponding creations were thought to have intervened between these greater catastrophes. All distinct species were then held to be new creations. The whole geological conception was thus made to consist of a series of catastrophes and creations in which the destructional and creative factors played alternate parts. Every tenure of existence was thought to be uncertain and the termination of the whole distinctly foreshadowed.

There was, indeed, some dissent from the catastrophic features of these views appearing now and then far back and growing as time went on. Hutton had urged the profound changes that could be wrought in time by the ceaseless action of the quiet agencies, and Lamarck had urged the divergencies of living forms that might be developed by use. Playfair had helped on the Huttonian views. Lyell near the end of the first quarter of the nineteenth century added further to these views and rounded out the whole into the doctrine of uniformitarianism which successfully contested the field with catastrophism during the second quarter of the nineteenth century and came to be the creed of the dominant school in the latter half of the century.

With the verity of the geological record firmly established, though incomplete, and with the competency of gentle agencies ceaselessly acting sustained by a strong advocacy, the way was prepared for a favorable reception of the doctrine of derivation of plant and animal species through selection when advanced by Darwin and Wallace near the middle of the century. Though this was essentially biological, the establishment of the geologic record was scarcely less than an indispensable prerequisite to any wide acceptance at that time. The profound educational effect of the doctrine of evolution into which this

has grown is perhaps quite as much due to geology as to biology so far as current times are concerned. The revolutionary effects of this doctrine of continuity and derivation in the intellectual world are familiar themes and need not be dwelt on here further than to urge their dependence on the verity of the larger history of which life evolution is a part. The full depth and reach of this revolution as an educational agency has not yet been realized and cannot be fully realized until the further evolutions to which it leads have had time to take tangible form and pass their trial periods.

The opening of the twentieth century has brought some of these further evolutions into tangible stages. These seem to foreshadow the issues of the present century. From the mystical ages down to the close of the eighteenth century, the earth and related bodies were commonly assigned a birth from chaos. During the nineteenth century, belief in a more orderly birth from gaseous or quasi-gaseous semichaotic states replaced these. In the closing stages of the nineteenth century the dynamics underlying all these cosmogonies was challenged and a system of dynamics of the same order as that which is now in control, entitled planetesimal because embodied in minute masses, offered in its stead. So also, instead of the previous assumption that the present solar system is the first and only system of its series, the firstborn of chaos, there was offered the hypothesis that the current solar system is but a rejuvenation of an earlier system back of which may lie a genealogy of systems to which no specific limit was assigned. It carries the conception of a slow-grown solid earth in which a molten earth or a general molten interior may probably never have been a feature. The preferential view is that internal stresses have constantly forced to the surface molten rock with its included gases as fast as formed in working volumes, thus building up the crust and feeding the atmosphere and hydrosphere, while the solidity of the interior is preserved. The atmosphere is made the product of cooperative agencies of supply and consumption whose mutual action maintains an oscillating equilibrium within limits congenial to terrestrial life, a system that presumably may continue to maintain the conditions of life for eons yet to come. This new phase of uniformitarianism opens a forecast of indeterminate duration corresponding to the enlarged retrospect it opens in the rejuvenations of past solar systems. The whole constitutes a further step in the reduction of the catastrophic factors and the extension of quiet persistent procedure. Even the rejuvenation of a solar system is made no more catastrophic than the mutually excitive effects of passing stars.

A second feature, a contribution of physics to geology, is the discovery that some of the atoms of the earth are undergoing spontaneous

disintegration and in doing so are shooting forth particles at prodigious velocities, implying energies of like prodigious order. This has raised the question, as yet unanswered, whether spontaneous change, and perhaps spontaneous organization, are not universal functions of earth matter and of the cosmic matter to which it is related. However this may be, the new phenomena exalt to the limit of man's imagination the activities and energies of common matter. In the light of this, the earth appears to have little need of an inheritance of internal heat, its volcanic displays may be little more than the product of spontaneous disintegration within. The energies of the solar system seem adequate for the greater projections backward and forward which the later cosmology had already assumed on other grounds.

This sketch of the growth of earth science implies the course of education through which the leaders of thought and the world at large have passed in reaching the present stage of world science. It is a concrete mode of indicating the place which this science has occupied in human progress. The phrase "world science" is here used permissively, for it is that rounded conception which embraces the totality of the earth and its inhabitants from the beginning till now, that has taken deep hold on the thought of the world and has influenced its intellectual development. The branches of earth study take their individual places as special sciences under the more comprehensive world study. These special geologic sciences embrace the subject-matter of most of the courses that form the curricula of the schools and require technical pedagogical treatment.

#### Deployment of the Geologic Sciences —

While the very essence of ideal geology is the unitary treatment of the organized totality of earth knowledge, its actual growth as a science and as a school study has diverged widely from this ideal. Particular phases of the subject have been taken up more or less sporadically as conditions invited, and this has given a lack of symmetry to its several stages. The geographic phase was the earliest, and geography might ideally have been extended to embrace the earth's composition, structure, processes, and life history, and so have embodied the whole group of earth sciences and the whole history of the earth, but in fact geographic studies were for ages so largely limited to the surface as it is, and to the present relations of the creatures that dwell on it, that the name came to denote this specifically and the term "geology" was coined to embrace the broader study that arose later.

The geographic mode of treatment is now being extended backward into the "geologic" ages and the old surfaces of the earth are being worked out, and so there is in process of development the new science of paleogeography. This is worked out almost wholly

by methods known as *geologic* and still the results are assembled and interpreted in a *geographic* sense and take that name

So, too, while the earlier geography was mainly descriptive of the earth surface as it is, with the growth of the spirit of inquiry into processes and antecedents, there has come into the later study a search for the origin and meaning of the surface features and so the old form of "geographic" treatment has grown more and more toward the "geologic" treatment, that is, toward the study of processes, former states, underlying material, structure, and historical meaning. And so the two sciences run together and overlap, as they should under the newer view of the true relations of the sciences and of their educational functions. The real fields of science overlap, interdigitate and interfuse, geography envelops the earth *in its way* and geology equally compasses the whole *in its way*; not a little of their common ground is identical, belonging equally to both and belonging exclusively to neither.

The ground where geography and geology most intimately meet is embraced under the terms physical geography and physiography. These terms are in part used synonymously and in part distinctively. When the emphasis is laid on the physical features of the surface as *features*, the better usage places the study under physical geography, when the emphasis is laid mainly on the mode of origin and the processes involved, the study takes on a geological aspect and is best placed under physiography as that term is used in America. With such a distinction in mind, physiography was placed in the geological group by those who were pioneers in the educational use of the term in America, while physical geography naturally retains its place in the geographic group.

Physiography is at once a recent school study and a recent development of geologic science. Powell and Gilbert, pioneers in enunciating the doctrine of the base level and of cycles of erosion, are worthy of being regarded as the fathers of the science, while Davis, Penck, Salisbury, and others have been efficient in developing it. As a means of training, it has the advantage of presenting an available field at the site of every institution, if urban modifications have not destroyed it. The processes that may be studied in action or through their recent results include a large portion of those that enter into stratigraphic and dynamic geology. As respects mental discipline, physiography is a rather rigorous naturalistic study of processes leading on to definite results and forcing rather close interpretations of results in terms of their causes. The actions are measurably complex but not usually so intricate as to confuse careful students. Physiographic study centers on physical processes and touches the biological and the human elements incidentally rather than

primarily. In this limitation it keeps on fairly solid grounds and trains students to firmness of mental action and trustworthiness in interpretation. These are its virtues. Its self-imposed limitation lies in leaving the biological and the human elements to be developed in similar ways on their own grounds. These cannot just yet be treated with the firmness and trustworthiness already attained on the physical side and, if they could, their fusion in a single work under a single title at this stage of educational development would be one of doubtful wisdom. It is therefore a mooted question how far the stronger treatment with its limitations should displace the looser treatment of the broader field pending the development of the biologic and anthropic elements on firmer grounds. The argument from supposed superior interest is scarcely pertinent, for superior interest usually lies where intellectual success finds its most tangible victories. The subject is touched again below.

When inquiry first seriously began to penetrate the earth, it took note of the composition and structure of the crust. This led to some knowledge of sedimentary rocks and to the beginning of stratigraphy and historical geology. It led also to a knowledge of volcanic, plutonic, and other crystalline rocks and thus to the geology of the massive terranes, the chief field of petrologic geology, the complement of stratigraphic geology. It led also to the recognition of bowed, warped, crumpled, broken, and shifted rocks and thus to deformative geology (diastrophism). This embraces the study of mountains (orogeny) and of the more general elevations and depressions (epeirogeny). Inquiry led also to the observation that distorted rocks have usually undergone crystallization and chemical modification and hence to metamorphic geology. The whole subject of geologic structure may be embraced under the sub-science geotectonics, and the whole of formational geology under that of geognosy. Vulcanology grew up naturally as a special phase of igneous geology, and seismology grew as naturally out of the study of rapid earth movements of which earthquakes are the most declared form. All these phenomena involve great energies and thus they tie geology to physics, the common borderland of which is treated under geophysics.

As the studies of the general aspects of rocks were carried down to detail it was discovered that the crust is composed of rock elements, conveniently known as rock species, and that these could be further analyzed into definite minerals, hence arose the science of rocks, lithology or petrology, or, when mainly descriptive, petrography, hence also arose the science of mineralogy, back of which lie closely chemistry and crystallography. Down to the latter half of the nineteenth century the study of rocks and minerals went but little beyond naked eye examinations, mechanical tests for

hardness, cleavage, and other qualities, and simple chemical tests supported in some degree by full chemical analyses, but optical methods were later introduced, particularly the examination of thin slices of rocks under a polarizing microscope, and this led to a much closer study of rocks and minerals and wrought a revolution in the sciences of mineralogy and petrology from which arose the sub-sciences optical mineralogy and optical petrography.

Petrology is almost inseparably connected with other branches of geology and is generally grouped with geology in university curricula. The relations of mineralogy are less declared. It is oftener grouped with geology than any other science, but it is sometimes associated with chemistry, sometimes made a distinct department, and sometimes, though rarely, coupled with physics on account of the optical factors. The best criterion in such cases of composite relationships is the very practical one of letting the source from which springs the largest student interest be the guide. In this respect the advantage lies largely with geology, for it is from geological phenomena that interest in minerals most largely springs, and it is in geology or in mining that mineralogy finds its largest applications.

The industrial and ornamental uses of rocks and minerals early gave rise to rude forms of economic geology and these utilities have steadily multiplied until this phase of geology has come to be one of wide application. It is the basis of governmental geological surveys and these have contributed greatly to the development of the science, not even excepting those of its phases that do not for the time being seem to have direct industrial importance. Through its economic phases, geology becomes related to several of the technological branches, as mining engineering, metallurgy, ceramics, architecture, etc.

The fundamental part that life relies played in the growth of the sciences implies, as suggested in the historical sketch, the educational relations of general geology to paleontology. When well deployed in an institution, paleontology usually falls into invertebrate paleontology, vertebrate paleontology, and paleobotany. The most recent science on the border line of biology and geology is ecology, a composite study of life in relation to its environment. As a study it is close akin to physiography, and the field work of the two is conveniently conjoined where both are well developed in the same institution. Physiography and plant ecology are natural running mates, and when ecology shall be extended to animals and man and treated on a firm basis, physiography, biologic ecology, and anthropic ecology will form a triumvirate of peculiar educational power and will doubtless set at rest the mooted question mentioned above by taking an indispensable position in standard curricula as effective disciplinary, as well as intellectually nourishing, studies.

When paleontology shall have gathered and elaborated adequate data relative to the psychological phenomena of past life, this will quite surely form the basis of paleopsychology, which will bind paleontologic geology to the modern mental sciences and cooperate with them in dealing with the earlier stages of mental, moral, and social development.

The study of the hydrosphere is a vital part of geology, for the activities of water in its various forms are the special characteristic of the present geologic eon. The geology of the hydrosphere grades into the special sciences of hydrology and oceanology, as also into glaciology and into physiography.

The atmosphere has long escaped an adequate treatment as a geological agent, but it is rapidly coming into its place and paleoclimatology and paleometeorology are foreshadowed sciences. Geological evidence of a cogent order is forcing an abandonment of inherited views on atmospheric phenomena and opening a place for these new sciences. It was thought until recently that the earth was enveloped by a thin atmosphere only, beyond which extremely cold and nearly empty space isolated it from its kin of the solar family. Closer inquiry makes it clear that the atmosphere is not so narrowly limited and that there is some exchange of matter between the members of the solar family. While it is not yet clear what quantitative value this exchange may have, it serves to bring the study of cosmologic relations into the present problems of geology, and to suggest that cosmology may come to play, in current issues, a part kindred to the more spectacular function played at the birth of the earth.

**Geology in the Schools** -- While the general geologic knowledge of the earlier ages grew up from the incidental observations of the multitude as they came into contact with the earth, geology as a formal study came into the higher horizons of the schools from the few who patiently worked it out into science, and it has gradually been working downward from higher to the lower horizons. A century ago geology scarcely had a recognized place in even the foremost institutions, save in certain economic aspects in certain schools of mines. Its growth as a distinct school study is almost compassed within the last hundred years, and much the most of the growth falls within the last half century. At first geology found a place only in the last years of study, and it has crept forward in the curriculum only slowly. The chief reason assigned for this retention of a late place is the need of studying so many other sciences before geology is taken up. While there is reason in this, the logic rests upon the doubtful assumption that it is best to proceed from science to phenomena rather than from phenomena to science. It remains to be seen whether the advantages of rotation and reciprocity in cultivating science may not be as conducive

to productiveness as they are in the cultivation of soils. The spread of geologic studies seems to have been more rapid down the upper horizons of different grades of institutions than down the courses of the same institution; and so at present, geology finds a place in the upper grades of secondary schools, while it rarely appears in the first years of the higher institutions. But in some form it now has a place in the best schools from the high school to the university.

*Geology and Physiography in the High Schools —*

A notable percentage of high schools in America are coming to offer courses in which the agents, processes, and stages of fashioning the earth's surface are factors. Whether this is done under the name physical geography, physiography, or geology is of minor importance. The order named seems to be that of predominance so far as the name is concerned. It is impracticable to ascertain precisely how the earth studies are handled on the average. It is safe to say, however, that the genetic phases of surface configuration, the vitalizing element, have rapidly gained in emphasis in recent years. The number of high schools that teach geological history is quite a minor fraction. With the growth of the study of surface fashioning processes, in essence dynamic geology, there has been a tendency to replace other forms of geology with this more special phase, a gain in intensity with a loss in breadth and in the biologic and human elements. This is a step in intensification whose value can only be fully seen when the complementary intensification in the biologic and anthropic factors, the plant, animal, and human ecologies, are brought into working order coordinately with physiography. Plant ecology is already coming into function as a companion study to physiography, and both are well adapted to the earlier years and form an excellent basis for the higher ecologies. These latter are in process of scientific development and will no doubt soon enter upon their early trial periods in the schools. These require greater breadth, equipoise, and maturity of judgment and are better adapted to the later years. They may well follow or go with historical geology, for historical geology brings into view the great facts of past ecological experience. The double couplet, physiography and insentiate ecology, earth history and sentient ecology, together cover in a strong way the ground covered in a more general fashion by physical geography, and constitute its appropriate successors in an effective curriculum.

Physiography and plant ecology converge in the phenomena of the soil, which is a special zone of contact. They come to be particularly intimate in the ecology of soil life, the critical point of advance in agriculture at present. They are the fundamental sciences on which soil science should rest and are therefore the sciences that may well be given in the high

schools as a preparation for agricultural science now pressing for a place in these schools. Animal ecology has a similar relation to the animal industries.

The present status of earth science in the secondary schools is eminently one of transition which, though marked by elements of confusion and some retrocession, is working rapidly toward a vitalization of geography by the introduction of the geologic element all down through the courses, by the introduction of physiography, and by the organization of the ecologies as more thorough treatments of vital phenomena on the earth's surface.

*In Normal Schools —* There is much difference in the work of the normal schools, but the standard state normal schools of America usually give courses in physiography or geology or both, and in some schools other geologic branches of the group are taught. The appointments are generally fair and field and laboratory work are commonly used as vitalizing elements. The introduction of strong courses in physiography and plant ecology in the early years and of historical geology and the higher ecologies in the later years will greatly aid in vitalizing geography and in leading on to the successful treatment of these subjects themselves in the high schools.

*In Colleges and Technical Schools —* Geology has a recognized place in the best colleges of America and in equivalent institutions elsewhere, though there are many weak colleges in which it has little or no place. In the stronger colleges it is deployed into mineralogy, physiography, petrology, general geology, and paleontology. Economic geology is not uncommonly given a place. Laboratory and field work are usual accompaniments. Geology is even accredited as an entrance study to some colleges. All colleges of standing are provided with mineralogical and geological collections. In the best colleges the full services of a professor, sometimes, though but rarely, with an assistant, are given to the geologic group, in many colleges, however, some other work is still associated with the geological.

In the technological schools not associated with universities, the place of the geological sciences varies from an amount comparable to that of the colleges to an amount comparable with the provisions of the better universities. Usually the emphasis is laid chiefly on mineralogy, petrography, and the structural, dynamical, and economic elements of geology. For these branches the appointments are usually good and the work in graphic, dynamic, and geometric lines is usually superior to that of most other institutions.

*In Universities —* The geologic sciences naturally find their largest place and their best deployment in the universities and in the technological institutes of comparable grade.

To form some idea of the relative place which the geologic sciences have attained in

the standard universities, a series of comparisons has been made between the sizes of the staffs of the several universities of the largest and of the medium types, and the total number of students in these institutions. It would be more satisfactory to compare the courses and the number of students in geology with the courses and students in other subjects, but the data are not available. In comparing the statistics relative to the staffs, teachers of mineralogy, petrology, paleontology, and geophysics are included with those of geology proper, except where these subjects are taught in other than the geologic senses, but teachers of geography are not included. The number of students used is, in all cases, the total attending the university. The data used were compiled chiefly from Trubner's *Minerva, Jahrbuch der gelehrten Welt*, for the year 1910-1911, with such revisions and additions as could be made from the official publications of the universities and from personal information. The results are to be regarded as a representative rather than as an exact exhibit.

In the comparison of the largest universities, an attendance of 3000 students was taken as the lower limit. Of this class there are 43 universities, distributed as follows: United States 16, Russia 6, Austro-Hungary 4, Germany 4, Great Britain 4, Italy 2, Spain 2, Argentina 1, Canada 1, France 1, Japan 1, and Roumania 1. In respect to total number of geologic teachers (those of professorial rank in parenthesis), the order is: United States (57) 96, Austro-Hungary (20) 26, Germany (17) 28,

Russia (12) 21, Great Britain (9), Roumania (5), France (4) 5, Argentina (3), Canada (3), Italy (2) 7, Japan 5, Spain (1) 2. The average number of geologic teachers per university is: Germany 7, Austro-Hungary 6.5, United States 6, France 5, Japan 5, Roumania 5, Italy 3.5, Russia 3.5, Argentina 3, Canada 3, Great Britain 2.25, Spain 1.

For the medium class, universities whose students range between 2000 and 3000 were selected. These serve better than the previous class to illustrate the development of geological instruction in the smaller countries and in universities located in the smaller cities where urban influences are less pronounced. There are 30 universities of this class distributed as follows: Germany 7, United States 6, France 4, Austro-Hungary 3, Belgium 2, Italy 2, Russia 2, Canada 1, Great Britain 1, Greece 1, Sweden 1.

In the aggregate number of geologic teachers (those of professorial rank in parenthesis), the order is as follows: Germany (19) 28, Italy (5) 15, France (10) 11, United States (9) 10, Austro-Hungary (7) 9, Russia (3) 6, Belgium (5), Canada (2), Great Britain (1), Greece (1), Sweden 1.

The average number of geologic teachers per university in this class is as follows: Italy 7.5, Germany 4, Austro-Hungary 3, Russia 3, Belgium 2.5, France 2.5, Canada 2, United States 1.7, Great Britain 1, Greece 1, Sweden 1.

The combined data for the two classes of universities, which embrace all that are attended by 2000 or more, are shown in the following table —

COMPARATIVE TABLE OF GEOLOGIC STAFFS OF UNIVERSITIES HAVING 2000 STUDENTS OR MORE

I	II	III	IV	V	VI	VII	VIII	IX
COUNTRY	POPULATION	NO OF UNIVERSITIES	TOTAL NO UNIVERSITY STUDENTS	NO OF GEOLOGIC PROFESSORS	TOTAL GEOLOGIC TEACHERS	AV NO PER UNIVERSITY	RATIO OF TEACHERS TO TOTAL STUDENTS	RATIO OF GEOLOGIC TEACHERS TO POPULATION
Austro-Hungary	27,995,000 (1907)	7	31,147	27	35	5	1 890	1 799,857
Belgium . . .	7,386,000 (1908)	2	5272	5	5	2.5	1 1054	1 1,477,200
Canada . . . .	7,185,000 (1909)	2	5280	5	5	2.5	1 1058	1 1,437,000
France . . . .	39,252,000 (1906)	5	27,882	14	16	3.2	1 1743	1 2,453,250
Germany . . . .	63,800,000 (1909)	11	46,379	36	56	5.1	1 828	1 1,139,286
Great Britain .	45,208,000 (1909)	5	13,752	10	10	2	1 1375	1 4,520,800
Italy	34,269,000 (1909)	4	14,588	7	22	5.5	1 663	1 1,557,682
Japan	49,769,000 (1909)	1	5649		5	5	1 1130	1 9,953,800
Roumania . .	6,700,000 (1908)	1	3878	5	5	5	1 776	1 1,340,000
Russia .	126,169,000 (1908)	8	37,564	15	27	3.4	1 1391	1 4,672,926
Spain . . . .	19,712,000 (1908)	2	9845	1	2	1	1 4923	1 9,856,000
Sweden .	5,377,000 (1907)	1	2056	1	3	3	1 685	1 1,792,333
United States	90,000,000 (1910)	22	87,433	66	106	4.8	1 825	1 849,056
Totals .	516,543,000	73	278,164	206	301	4.1	1 897	1 1,666,268

The average geologic staff for the 73 universities is 4.1. The largest staff numbers 17. The average ratio of geologic teachers to students in the whole 73 universities is 1:897. The best ratio in a single university is 1:250. The ratio in the university that has the largest staff is 1:412.

An inspection of similar data for previous years shows that there has been a very rapid increase in the provisions for geological instruction, particularly in the United States.

**Educational Methods** — Geological education takes on two distinct phases, (1) instruction at the institution and (2) training in the field. The intramural work takes the form of lectures, class discussions, quizzes, conferences, personal work, seminars, and clubs. Lectures hold a large place and must apparently continue to do so in those branches where the material of instruction is not yet well organized. Systematic quizzes are used by many teachers as a supplement to lectures. Class discussion and group conferences are felt by many to be the most efficient mode of training when the subject matter is in suitable form. Conferences are particularly applicable to map study where only small groups are permissible. Personal instruction where the work can be made individual, as in laboratory, experimental, and thesis work, is widely employed. Seminars for advanced work and clubs for reports of individual work, critiques, discussions, lectures not in course, especially lectures by visiting geologists, are valuable adjuncts. Courses in drawing and in graphic work are given in some universities. (2) Field work is a distinctive feature of the most effective geologic training. This falls into two classes, the circum-institutional and the remote. The first is often immediately associated with the classroom courses and is then arranged so as to fit in with the program of the latter. It is also arranged independently into systematic courses occupying certain days of the week. Occasional excursions, not exceeding a day's duration, fall into the circum-institutional class. The distant field work is handled in a more varied way. Often it consists only of special excursions of a few days' duration, which are stimulative but not adapted to close training. Of the more systematic work a three-course system is perhaps the best representative in actual use. (1) In this, the first course is shaped to follow the earlier classroom courses. It consists of a systematic study of a selected area in the manner of official geological surveys, and is followed by a report on the work by each student participating. The time ranges from a month upward, and the area is preferably one of the quiet type, not too plainly exposed, nor too intricate, suited to promote careful search for data and yet to yield decisive results to diligent students. (2) The second course consists preferably of work on a larger, more complex, and more impressive area suited to develop

larger and more intricate conceptions, and to be the basis of reports of a broader type. Both these courses are under the immediate direction of competent leaders, and the numbers participating are limited to those whose work can be individually supervised. (3) The third course is individual, and is often the basis of the Doctor's thesis. The selection of the area, the plan of work, the choice of problems, and the style of report are chosen by the student under the criticism of the specialist in the line chosen, original independent work being here the chief end sought. The report is expected to be elaborate and presumed to be representative of the student's best capabilities.

Special courses in topographic and geologic mapping are given in the best institutions, sometimes in connection with these field courses, and sometimes independently. Special paleontological or other specific field courses are sometimes given. Incidentally, field work is often done in vacations in connection with official or other geological surveys.

The advanced work in geology is chiefly done in the graduate schools. In the standard institutions it involves at least three years' work in addition to the more general and elementary work of the undergraduate courses. Theses of three kinds are prepared, though rarely all in the same institution, one preliminary to the Bachelor's degree at the close of the undergraduate course, one preliminary to the Master's degree after one or more years of graduate work, and one prerequisite to the Doctor's degree for which three years of graduate work is usually required.

**Appliances** — Equipment for geological work centers upon an effort to bring nature as close to the student as possible, and, next after field work, three classes of appliances are resorted to: (1) actual samples, (2) models, and (3) photographs. Collections more or less varied and extensive are common possessions. Practice varies in the emphasis laid on museum exhibits and on classroom and laboratory collections respectively; a merely synoptic exhibit in the museum, to give distinct impressions of the types, and large working collections and illustrative collections in drawers and in the classrooms and laboratories are urged by some experienced teachers. A museum so located that the students are naturally brought into constant contact with it is also urged. Models play a large part in a satisfactory equipment, especially relief models and raised maps. Photographic art has made valuable contributions here as in other sciences, ample collections of photographs systematically arranged for study, photographic wall exhibits and transparencies, and especially lantern slides with lantern fixtures ready for prompt use as required are indispensable adjuncts.

For special classes of work the requisites for efficiency generally possessed by the standard

universities include: For mineralogical, petrologic, structural, and paleontological work, laboratories and laboratory appliances, embracing working collections, models, testing tools, blowpipe outfits, chemicals, rock-slicing machines, microscopes, goniometers, photographic and other appliances; for map study, conference tables and map stacks in cases that facilitate access; for classroom work, wall exhibits of maps, sections, photographs, transparencies, globes, plain and in relief, with ample lantern outfit; for museum study, exhibit collections and drawer collections in various lines; for all classes of study an ample library well supplied with maps and preferably organized as a departmental library, well situated in the midst of the geologic rooms and used as the students' working home

**Educational Literature** — The available literary material in the geological sciences has been greatly enriched in recent years. Revisions of standard works have been frequent and new treatises have been added at short intervals. The formulated literature of the science in its more general aspects does not lag far behind the science itself. These formal educational works are supplemented by geological journals, some of which are published under the auspices of educational institutions and are edited with a special view to educational service. Bulletins giving the results of researches are published by some universities. In the broader educational sense, the numerous official surveys are effective agencies and their reports are a leading source of working material. Some of these reports are especially shaped for educational purposes. So, too, the geological societies, both in themselves and in their publications, are great educational aids, especially in that they are a means of education of the educators, a function of the most radical value. **GEOMETRY.** — Etymologically the word means earth measure, from the Greek  $\gamma\eta$ ,  $g\tilde{e}$ , earth +  $\mu\acute{\epsilon}\tau\rho\nu$ , *metron*, measure. It has come, however, to mean the general science of form,

the words "surveying" and "geodesy" being applied to the measuring of the earth.

**History of Geometry** — The earliest documents relating to geometry come to us from Babylon and Egypt. Those from Babylon are written on small clay tablets, some of them about the size of the hand, these tablets afterwards having been baked in the sun. They show that the Babylonians of that period knew something of land measures, and perhaps had advanced far enough to compute the area of a trapezoid. For the mensuration of the circle they later used, as did the early Hebrews, the value  $\pi = 3$ . A tablet in the British Museum shows that they also used such geometric forms as triangles and circular segments in astrology or as talismans, and a stone astrolabe in the same collection shows that they knew something of angle measure.

The Egyptians must have had a fair knowledge of practical geometry long before the date of any mathematical treatise that has come down to us, for the building of the pyramids, between 3000 and 2400 B. C., required the application of several geometric principles. Some knowledge of surveying must also have been necessary to carry out the extensive plans for irrigation that were executed under Amenemhat III, about 2200 B. C.

The first definite knowledge of Egyptian mathematics is based on a manuscript copied on papyrus, a kind of paper used about the Mediterranean in early times. This copy was made by one Aah-mesu (The Moon-born), commonly called Ahmes ( $q v$ ), who probably flourished about 1700 B. C. The original from which he copied, written about 2300 B. C., has been lost, but the papyrus of Ahmes, written nearly four thousand years ago, is still preserved, and is now in the British Museum. In this manuscript, which is devoted chiefly to fractions and to a crude algebra, is found some work on mensuration. Among the curious rules are the incorrect ones that the area of an isosceles triangle equals half the product of the base and one of the equal sides, and that the area of a trapezoid having bases  $b$ ,  $b'$ , and the nonparallel sides each equal to  $a$ , is  $\frac{1}{2} a (b + b')$ . One noteworthy advance appears, however. Ahmes gives a rule for finding the area of a circle, substantially as follows. Multiply the square on the radius by  $(\frac{25}{8})^2$ , which is equivalent to taking for  $\pi$  the value 3.1605. This papyrus also contains some treatment of the mensuration of solids, particularly with reference to the capacity of granaries. There is also some slight mention of similar figures, and an extensive treatment of unit fractions, — fractions that were quite universal among the ancients. (See FRACTIONS.) Herodotus tells us that Sesostris, king of Egypt, divided the land among his people and marked out the boundaries after the overflow of the Nile, so that surveying must have been well known in his day. Indeed, the *harpedonaptæ*, or rope

stretchers, acquired their name because they stretched cords in which were knots, so as to make the right triangle 3, 4, 5, when they wished to erect a perpendicular. This is a plan occasionally used by surveyors to-day, and it shows that the practical application of the Pythagorean theorem was known long before Pythagoras gave what seems to have been the first general proof of the proposition.

From Egypt, and possibly from Babylon, geometry passed to Asia Minor and Greece. The scientific study of the subject begins with Thales (*qv*). How elementary the knowledge of geometry then was may be understood from the fact that tradition attributes to him only about four propositions. The greatest pupil of Thales, and one of the most remarkable men of antiquity, was Pythagoras (*qv*). In geometry he is said to have been the first to demonstrate the proposition that the square on the hypotenuse is equal to the sum of the squares upon the other two sides of a right triangle. The proposition was known in India and Egypt before his time, at any rate for special cases, but he seems to have been the first to prove it. To him or to his school seems also to have been due the construction of the regular pentagon and of the five regular polyhedrons. Pythagoras is also said to have known that six equilateral triangles, three regular hexagons, or four squares, can be placed about a point so as just to fill the  $360^\circ$ , but that no other regular polygons can be so placed. To his school is also due the proof for the general case that the sum of the angles of a triangle equals two right angles.

For two centuries after Pythagoras geometry passed through a period of discovery of propositions. The state of the science may be seen from the fact that Oenopides of Chios, who flourished about 465 B.C., and who had studied in Egypt, was celebrated because he showed how to let fall a perpendicular to a line, and how to make an angle equal to a given angle. A few years later, about 440 B.C., Hippocrates of Chios wrote the first Greek textbook on mathematics. He knew that the areas of circles were proportional to the squares on their radii, but was ignorant of the fact that equal central angles or equal inscribed angles intercept equal arcs. Antiphon and Bryson, two Greek scholars, flourished about 430 B.C. The former attempted to find the area of a circle by doubling the number of sides of a regular inscribed polygon, and the latter by doing the same for both inscribed and circumscribed polygons. They thus approximately exhausted the area between the polygon and the circle, and hence this method is known as the method of exhaustions. About 420 B.C. Hippias of Elis invented a certain curve called the quadratrix, by means of which he could square the circle and trisect any angle. This curve cannot be constructed by the unmarked straightedge and the compasses, and when we

say that it is impossible to square the circle or to trisect any angle, we mean that it is impossible by the help of these two instruments alone.

During this period the great philosophic school of Plato (429–348 B.C.) flourished at Athens, and to this school is due the first systematic attempt to create exact definitions, axioms, and postulates, and to distinguish between elementary and higher geometry. It was at this time that elementary geometry became limited to the use of the compasses and the unmarked straightedge, which took from this domain the possibility of constructing a square equivalent to a given circle ("squaring the circle"), of trisecting any given angle, and of constructing a cube that should have twice the volume of a given cube ("duplicating the cube"), these being the three famous problems of antiquity. One of Plato's pupils was Philip-pus of Mende, in Egypt, who flourished about 380 B.C. It is said that he discovered the proposition relating to the exterior angle of a triangle. His interest, however, was chiefly in astronomy. Another of Plato's pupils was Eudoxus of Cnidus (408–355 B.C.). He elaborated the theory of proportion, placing it upon a thoroughly scientific foundation. It is probable that Book V of Euclid, which is devoted to proportion, is essentially the work of Eudoxus.

The first great textbook on geometry, and the greatest one that has ever appeared, was written by Euclid (*qv*). In his work Euclid placed all of the leading propositions of plane geometry then known, and arranged them in a logical order. Most geometries of any importance written since his time have been based upon Euclid, improving the sequence, symbols, and wording as occasion demanded.

The Greeks contributed little more to elementary geometry, although Apollonius of Perga (*qv*), who taught at Alexandria between 250 and 200 B.C., wrote extensively on conic sections, and Hypsicles of Alexandria, about 190 B.C., wrote on regular polyhedrons. Hypsicles was the first Greek writer who is known to have used sexagesimal fractions, — the degrees, minutes, and seconds of our angle measure. Zenodorus (180 B.C.) wrote on isoperimetric figures, and his contemporary, Nicomedes of Gerasa, invented a curve known as the conchoid, by means of which he could trisect any angle. Another contemporary, Diocles, invented the cissoid, or ivy-shaped curve, by means of which he solved the famous problem of duplicating the cube; that is, of constructing a cube that should have twice the volume of a given cube.

The greatest of the Greek astronomers, Hipparchus (*qv*, 180–125 B.C.), lived about this period, and with him begins spherical trigonometry as a definite science. A kind of plane trigonometry had been known to the ancient Egyptians. The Greeks usually employed the chord of an angle instead of the

half chord (sine), the latter having been preferred by the later Arab writers. The most celebrated of the later Greek physicists was Heron of Alexandria (*qv*), formerly supposed to have lived about 100 B.C., but now assigned to the first century A.D. His contribution to geometry was the formula for the area of a triangle in terms of its sides  $a$ ,  $b$ , and  $c$ , with  $s$  standing for the semiperimeter  $\frac{1}{2}(a + b + c)$ . The formula is  $\sqrt{s(s-a)(s-b)(s-c)}$ . Probably nearly contemporary with Heron was Menelaus of Alexandria, who wrote a spherical trigonometry. He gave an interesting proposition relating to plane and spherical triangles, their sides being cut by a transversal. For the plane triangle  $ABC$ , the sides  $a$ ,  $b$ , and  $c$  being cut respectively in  $X$ ,  $Y$ , and  $Z$ , the theorem asserts substantially that

$$\frac{AZ}{BZ} \cdot \frac{BX}{CX} \cdot \frac{CY}{AY} = 1.$$

The most popular writer on astronomy among the Greeks was Ptolemy (Claudius Ptolemæus, *qv*, 87-165 A.D.), who lived at Alexandria. He wrote a work entitled *Megale Syntaxis* (*The Great Collection*), which his followers designated as *Megistos* (greatest), on which account the Arab translators gave it the name *Almagest* (*al* meaning "the"). He advanced the science of trigonometry, but did not contribute to geometry. At the close of the third century Pappus of Alexandria (*qv*) wrote on geometry. Only two other Greek writers need be mentioned. Theon of Alexandria (370 A.D., *qv*), the father of the Hypatia (*qv*) who is the heroine of Charles Kingsley's well-known novel, wrote a commentary on Euclid to which we are indebted for some historical information. Proclus (412-485 A.D., *qv*) also wrote a commentary on Euclid, and much of our information concerning the first Book of Euclid is due to him.

The East did little for geometry, although contributing considerably to algebra. The first great Hindu writer was Aryabhatta (*qv*), who was born in 476 A.D. He, or a later namesake of his, gave the very close approximation for  $\pi$ , expressed in modern notation as 3.1416. He also gave rules for finding the volume of the pyramid and sphere, but they were incorrect, showing that the Greek mathematics had not yet reached the Ganges. Another Hindu writer, Brahmagupta (born in 598 A.D., *qv*), wrote an encyclopedia of mathematics. He gave a rule for finding Pythagorean numbers, expressed in modern symbols as follows.—

$$\frac{1}{4}\left(\frac{p^2}{q} + q\right)^2 = \frac{1}{4}\left(\frac{p^2}{q} - q\right)^2 + p^2.$$

He also generalized Heron's formula by asserting that the area of an inscribed quadrilateral of sides  $a$ ,  $b$ ,  $c$ ,  $d$ , and semiperimeter  $s$ , is  $\sqrt{(s-a)(s-b)(s-c)(s-d)}$ .

The Arabs did much for mathematics, translating the Greek authors into their language and also bringing learning from India. Indeed, it is to them that modern Europe owed its first knowledge of Euclid. They contributed nothing of importance to elementary geometry, however. The greatest of the Arab writers was Mohammed ibn Musa al-Khowarazmi (820 A.D., *qv*), who lived at Bagdad and Damascus. Although chiefly interested in astronomy, he wrote the first book bearing the name *algebra* (*Al-gebr w'al-mugabala*, Restoration and Equation), composed an arithmetic using the Hindu numerals, and paid much attention to geometry and trigonometry.

Euclid was translated from the Arabic into Latin in the twelfth century, Greek manuscripts not being then at hand, or being neglected because of ignorance of the language. The leading translators were Adelhard of Bath (1120, *qv*), an English monk, Gherardo of Cremona (1160), an Italian monk; and Johannes Campanus (1250), chaplain to Pope Urban IV. The greatest European mathematician of the Middle Ages was Leonardo of Pisa (See FIBONACCI, LEONARDO). He was very influential in making the Hindu-Arabic numerals known in Europe. He wrote extensively on algebra, and was the author of one book on geometry, but he contributed nothing to the elementary theory. The first edition of Euclid was printed in Latin in 1482, the first one in English appearing in 1570.

There has of late arisen a modern elementary geometry devoted chiefly to special points and lines relating to the triangle and the circle, and many interesting propositions have been discovered. The subject is so extensive that it cannot find any place in our crowded curriculum, and must necessarily be left to the specialist. Some idea of the nature of the work may be obtained from a mention of a few propositions.

The bisectors of the various interior and exterior angles of a triangle are concurrent by threes in the incenter or in one of the three excenters of the triangle.

The common chord of two intersecting circles is a special case of their radical axis, and tangents to the circles from any point on the radical axis are equal.

If  $O$  is the orthocenter of the triangle  $ABC$ , and  $X$ ,  $Y$ ,  $Z$  are the feet of the perpendiculars from  $A$ ,  $B$ ,  $C$  respectively, and  $P$ ,  $Q$ ,  $R$  are the mid-points of  $a$ ,  $b$ ,  $c$  respectively, and  $L$ ,  $M$ ,  $N$  are the mid-points of  $OA$ ,  $OB$ ,  $OC$  respectively, then the points  $L$ ,  $M$ ,  $N$  —  $P$ ,  $Q$ ,  $R$  —  $X$ ,  $Y$ ,  $Z$ , all lie on a circle, the "nine points circle."

**Reasons for Studying Geometry** — It has always been held that geometry is studied because of a peculiar training and pleasure that this science gives, and that other sciences do not give, at least in the same degree. With the investigations of modern psychologists there has come a doubt as to the value of the

training that it gives, and this has led many emotional followers of new doctrines to proclaim that geometry has no such claim upon the pupil's time as the advocates of this value assert. Modern educators do not claim, however, that geometry has no value *per se*, but rather that the methods of presenting the subject that have obtained in the past can be improved, and that certain of the values formally claimed for it do not exist. To this the more thoughtful teachers of the subject have long since assented. For example, it was poor policy to memorize all of geometry, for this plan took away the pleasure of the study, and it did not give the pupil any power that he could carry over into other lines of work, save as he acquired facts which he could have obtained as well without the labor of memorizing the proofs of Euclid.

The advocates of a substantial geometry, as opposed to the mere acquisition of a few rules of mensuration, claim that the study of geometry brings great pleasure and an inspiring mental uplift, when the subject is properly presented. They place it in this respect upon a plane similar to that upon which the study of literature and music rests. They further claim that through geometry a student acquires a knowledge of space relations that he does not acquire from other subjects, which knowledge he carries over into the study of the graphic and plastic arts, of geography and astronomy, and of the science of mechanics. They also assert that geometry is the only subject in the secondary curriculum that gives a specific training in deductive logic, and that this training gives a habit of thought that is carried over into other lines of mental activity. And finally they claim that habits of persistence, of using only the necessary steps in an argument, of holding to that which is true, of seeking for exact truth, and of arranging work in logical order, are instilled by the study of geometry, and that these habits are unconsciously transferred to other fields of work. In other words, they claim that the pleasure and the profit of approach to exact truth give a power that makes the pupil stronger in his other activities. This claim is sanctioned by the opinions of most people who have studied geometry under a worthy teacher, and no investigations thus far made have shaken it. The statement that geometry has no value as a mental discipline is usually found to mean that there is no such thing as mental discipline as defined by the antagonist, to which most people would heartily agree.

#### Development of the Teaching of Geometry.

— Little is known of the teaching of geometry in very ancient times, but its nature can be inferred from the teaching that is still seen in the native schools of the East. Here a man, learned in any science, will have a group of voluntary students sitting about him, and to them he will expound the truth. Such schools

may still be seen in India, Persia, and China, the master sitting on a mat placed on the ground or on the floor of a veranda, and the pupils reading aloud or listening to his words of exposition.

In Greece it was taught in the schools of philosophy, often as a general preparation for philosophic study. Thus Thales introduced it into his Ionian school, Pythagoras made it very prominent in his great school at Crotona in southern Italy (Magna Græcia), and Plato placed above the door of his *Academia* the words, "Let no one ignorant of geometry enter here" — a kind of entrance examination for his school of philosophy. In these gatherings of students it is probable that geometry was taught in much the same way as that already mentioned for the schools of the East, a small group of students being instructed by a master. But with these crude materials there went an abundance of time, so that a number of great results were accomplished in spite of the difficulties attending the study of the subject. It is said that Hippocrates of Chios (c 440 B.C.) wrote the first elementary textbook on mathematics and invented the method of geometric reduction, the replacing of a proposition to be proved by another, which, when proved, allows the first one to be demonstrated. A little later Eudoxus of Cnidus (c 375 B.C.), a pupil of Plato's, used the *reductio ad absurdum*, and Plato is said to have invented the method of proof by analysis, an elaboration of the plan used by Hippocrates. Thus these early philosophers taught their pupils, not facts alone, but methods of proof, giving them power as well as knowledge. Furthermore, they taught them how to discuss their problems, investigating the conditions under which they are capable of solution. This feature of the work they called the *diorismus*, and it seems to have started with Leon, a follower of Plato. Between the time of Plato (c 400 B.C.) and Euclid (c 300 B.C.) several attempts were made to arrange the accumulated material of elementary geometry in a textbook. Plato had laid the foundations for the science, in the form of axioms, postulates, and definitions, and he had limited the instruments to the straightedge and the compasses. Aristotle (c 350 B.C.) had paid special attention to the history of the subject, thus finding out what had already been accomplished, and had also made much of the applications of geometry.

Of the other Greek teachers there is but little information as to methods of imparting instruction. It is not until the Middle Ages that much is known in this line. Whatever of geometry was taught seems to have been imparted by word of mouth in the way of expounding Euclid, and this was done in the ancient fashion. The early Church leaders usually paid no attention to geometry, but as time progressed the *quadrivium*, or four sciences of arithmetic, music, geometry, and astronomy,

came to rank with the *trivium* (grammar, rhetoric, dialectics), the two making up the seven liberal arts (*q.v.*). All that there was of geometry in the first thousand years of Christianity, however, at least in the great majority of Church schools, was summed up in a few definitions and rules of mensuration. Gerbert (*q.v.*), who became Pope Sylvester II in 999 A.D., gave a new impetus to geometry by discovering a manuscript of the old Roman surveyors and a copy of the geometry of Boethius (*q.v.*) who paraphrased Euclid about 500 A.D. He thereupon wrote a brief geometry, and his elevation to the papal chair tended to bring the study of mathematics again into prominence.

Geometry now began to have some place in the Church schools, naturally the only schools of high rank in the Middle Ages. The study of the subject, however, seems to have been merely a matter of memorizing. Geometry received another impetus in the book written by Leonardo of Pisa (see FIBONACCI, LEONARDO) in 1220, the *Practica Geometriae*. Euclid was also translated into Latin about this time (strangely enough, as already stated, from the Arabic instead of the Greek), and thus the treasury of elementary geometry was opened to scholars in Europe. From now on, until the invention of printing (*c.* 1450), numerous writers on geometry appear, but so far as is known the method of instruction remained much as it had always been. The universities began to appear about the thirteenth century, and Sacrobosco (*q.v.*), a well-known medieval mathematician, taught mathematics about 1250 in the University of Paris. In 1336 this university decreed that mathematics should be required for a degree. In the thirteenth century Oxford required six books of Euclid for one who was to teach, but this amount of work seems to have been merely nominal, for in 1450 only two books were actually read. The universities of Prague (founded in 1350) and Vienna (*Statutes* of 1389) required most of plane geometry for the teacher's license, although Vienna demanded but one book for the bachelor's degree. So, in general, the universities of the thirteenth, fourteenth, and fifteenth centuries required less for the degree of master of arts than is now required from a pupil in American high schools. On the other hand, the university students were younger than now, and were really doing only high school work.

The invention of printing made possible the study of geometry in a new fashion. It now became possible for any one to study from a book, whereas before this time instruction was chiefly by word of mouth, consisting of an explanation of Euclid. The first Euclid was printed in 1482, at Venice, and new editions and variations of this text came out frequently in the next century. Practical geometries became very popular, and the reaction against

the idea of mental discipline threatened to abolish the old style of text. Such writers as Finæus (1556), Bartoli (1589), Belli (1569), and Cataneo (1567), in the sixteenth century, and Capra (1673), Gargioli (1655), and many others in the seventeenth century, either directly or inferentially took this attitude towards the subject.

The study of geometry in the secondary schools is relatively recent. The Gymnasium at Nuremberg, founded in 1526, and the Cathedral school at Wurttemberg (as shown by the curriculum of 1556), seem to have had no geometry before 1600, although the Gymnasium at Strassburg included some of this branch of mathematics in 1578, and an elective course in geometry was offered at Zwickau, in Saxony, in 1521. In the seventeenth century geometry is found in a considerable number of secondary schools, as at Coburg (1605), Kurpfalz (1615, elective), Erfurt (1643), Gotha (1605), Giessen (1605), and numerous other places in Germany, although it appeared but rarely in the secondary schools of France before the eighteenth century. In Germany the *Realschulen* came into being in the eighteenth century, and considerable effort was made to construct a course in geometry that should be more practical than that of the modified Euclid. At the opening of the nineteenth century the Prussian schools were reorganized, and from that time on geometry has had a firm position in the secondary schools of all Germany. In the eighteenth century some excellent textbooks on geometry appeared in France, among the best being that of Legendre (1794), which influenced in such a marked degree the geometries of America. Soon after the opening of the nineteenth century the *lycées* of France became strong institutions, and geometry, chiefly based on Legendre, was well taught in the mathematical divisions. A worthy rival of Legendre's geometry was the work of Lacroix, who called attention continually to the analogy between the theorems of plane and solid geometry, and even went so far as to suggest treating the related propositions together in certain cases.

In England the secondary schools, such as Rugby, Harrow, and Eton, did not commonly teach geometry until quite recently, leaving this work for the universities. In Christ's Hospital, London, however, geometry was taught as early as 1681, from a work written by several teachers of prominence. The highest class at Harrow studied "Euclid and vulgar fractions" one period a week in 1829, but geometry was not seriously studied before 1837. In the Edinburgh Academy as early as 1835, and in Rugby by 1839, plane geometry was completed.

Not until 1844 did Harvard require any plane geometry for entrance. In 1855 Yale required only two books of Euclid. It was therefore from 1850 to 1875 that plane geometry took its definite place in the American secondary school.

**Present Status of the Teaching of Geometry** — Plane geometry is now commonly taught in the United States in the tenth school year, the second year of a four-year high school. This is usually followed by a half year of solid geometry, frequently elective. It is not the universal custom to finish all of plane geometry in a single year, although this is done in many of the best schools, and it probably represents the future curriculum as to the amount of time to be allowed to the subject. There is at present a tendency to reduce the number of basal propositions and to increase the number of exercises, so as to give a student more opportunity for independent work. The Eastern colleges do not require solid geometry for entrance to the arts course, while the Western ones frequently do require it. This means that more work is covered in plane geometry in the secondary schools of the Eastern states, the amount of time spent on the entire subject of geometry being about the same. From every standpoint it would be better that a pupil should sacrifice some of plane geometry for the purpose of having an introduction to solid geometry, if he could acquire the latter only in this manner.

Certain attempts have been made to teach algebra and geometry simultaneously, or even to fuse them into a single subject. This has usually met with only sporadic success. That the foreign schools have usually run geometry over several years, as opposed to the American plan, is liable to be misunderstood. Where serious demonstrative geometry has been begun early and extended over several years, the results have not been satisfactory. Usually the early geometry has been mere mensuration, a subject that is taught in the American arithmetic, and that is coming to be very satisfactorily taught. It may therefore be said that in America geometry extends over several years, culminating in a year or a year and a half of serious demonstrative work. As to the fusing of the two subjects of algebra and geometry in one, this seems destined to meet with success only in schools in which nothing but a little practical geometry is studied.

The question of the nature of the textbook is one that is periodically agitated. Several types have been suggested: (1) A book with the basal proofs substantially in full, to serve as models, and a large number of well-graded exercises for original work; (2) a syllabus of basal propositions; (3) a book of suggested proofs, heuristic in nature. Of these the first has been the one almost universally used, the objections to it having little force with a good teacher, and the other forms being useless with a poor teacher.

**Reforms and Improvements.** — Numerous reforms and improvements are being suggested for the treatment of geometry at the present time, and a few of these will be mentioned. (1) That geometry and algebra be fused into

a single subject, an effort that takes no account of the fact that the two subjects are distinct in purpose, in results, and in difficulty, and that each has a peculiar interest that is lost when it sacrifices its individuality. (2) That the two subjects be taught simultaneously, two days of one and three of the other during each school week. This has often been tried in the United States, but in the main with unsatisfactory results. Psychologically the argument is that the pupil is not mature enough for this plan, his interest being better maintained by concentrating his energy on either the one or the other. The argument that he would see the relation of one science to the other better by the simultaneous than the tandem arrangement is offset by the custom of the best teachers to bring into algebra as much of the mensuration learned in arithmetic as possible, and to introduce into geometry as many applications of algebra as seem adapted to this purpose. (3) That geometry be converted into an applied science, joining the general industrial movement of the present. This would mean that geometry would cease to exist, since the applications of the subject are merely the rules of mensuration learned in arithmetic, and learned by a natural form of induction. If geometry were abolished it would be possible to introduce other lines of mathematics, such as trigonometry (which requires only very little geometry), calculus (which requires practically no geometry beyond elementary mensuration for a large number of its applications), and some little work in the practical problems of vector analysis. For the great majority of students this seems unwise, since they have little interest in these applications, but in certain forms of technical high schools such an arrangement may prove necessary. (4) That algebra be taught for a half year, followed by geometry for the same length of time, and this by another half year of algebra, followed again by a half year of geometry. This plan has certain advantages over the year arrangement, but as yet it has to justify itself, the general feeling being that the pupil would lose more in immediate interest in a topic than he would gain in sustained interest in mathematics as a whole.

While these suggestions for reform are open to question, other reforms are meeting with general acceptance and are improving the current teaching of geometry. (1) It is universally agreed that Euclid is undesirable as a textbook for beginners, and, even in England where it has so long been the standard, it is now superseded by books more suited to the youthful mind. (2) The propositions of the textbook are coming to be considered more in the light of basal truths, and the proofs as models, and the serious work of the pupils is coming to be more and more in the realm of exercises. (3) The exercises are coming to be more carefully grouped and graded.

(4) Such legitimate applications as can be found, and as give interest to the study of geometry, are being sought for and introduced  
(5) More attention is being given to geometric design, so long as this does not detract from the scientific work. (6) In brief, serious effort is being made to make geometry more interesting and useful, and to recognize its game element and its utility, without destroying the values that have long made it a recognized standard subject in the curriculum

**GEORGE III** — See LANCASTER, JOSEPH

**GEORGE JUNIOR REPUBLIC, FREEVILLE, N.Y.** — An organization of boys and girls modeled on the government of the United States. It arose out of the summer camps first begun in 1890 by Mr William R George, who had for several years studied the "boy problem" among the New York street urchins. One experience after another with the worst type of city boys who regarded charity as their right, who had no moral sense, whose chief aim was to secure something for nothing, led Mr. George from one system of control to another, until he recognized that boys, and girls too, must own something which they valued, that the basis of government is property, that there should be nothing without labor, and that

this small community must learn to govern itself. The permanent Republic was launched in the summer of 1895, five boys remaining with Mr George after summer camp. This number gradually rose until now the village numbers about 150 citizens. In 1896 the George Junior Republic Association was incorporated and a farm was purchased. The government was placed in the hands of the community, a president, vice-president, judge, chief of police, secretary of state, and secretary of the treasury, and a legislature were elected, important practical questions arose and were settled, such as the question of currency, woman's suffrage, and trusts. When it was found that the members of the legislature were not always disinterested, a monthly town meeting was substituted. In all other respects the village is a copy in miniature of the outside world with its trade, commerce, and industries. The citizens are drawn from all classes; boys and girls committed by sentence of a court, wayward juveniles sent by their parents, boys and girls who come voluntarily to the Republic to find there a start which is so difficult for them outside. But there are no distinctions of class, all must work to support themselves or be maintained in the workhouse or jail, where they are compelled to labor. The chief industries of the Republic are farming, carpentry, plumbing, printing, baking, road-mending and building, laundry and domestic work for the girls. The community is housed in ten cottages and hotels, and is provided with board and lodging according to their means. There is a special currency and a bank, the savings may be redeemed in United States currency on leaving the village. A school is maintained which provides instruction up to college entrance requirements. There is a chapel in which each denomination has its own service. An interesting feature of the Republic is the court in which offenders are tried by a jury of their peers, the judge is an elected officer. Law-breakers may be fined or imprisoned in the jail which adjoins the court. Mr George attributes the success of the experiment to the absence of an adult-manufactured system. Those characteristics which mark boy and girl life generally are seized upon as the foundation. There is no adult interference with the exception that the larger industrial undertakings are in the charge of adult and experienced helpers, while the spirit of home life is introduced into the cottages by the presence of adult proprietors. The institution is maintained through payment for board by parents, guardians, societies, or county officials, annual contributions, a small endowment, payment towards teachers' salaries from the State Education Department, and income from sales of products made by the citizens. The success of the institution is evidenced by the fact that of those who have been through the Republic only about two per cent have turned

out to be failures, while the rest are to be found in all walks of life, a few having proceeded to Cornell, Harvard, Columbia, and other colleges.

In 1908 the National Association of Junior Republics was formed to encourage the establishment of republics in other parts of the country. The Carter Republic at Redington, Pa., and the National Republic at Annapolis Junction, Md., may be mentioned as carrying out work on the same principle as the George Junior Republic.

**GEORGE WASHINGTON UNIVERSITY, WASHINGTON, D C** — The successor of the Columbian College of the District of Columbia, an institution chartered by Congress on Feb. 9, 1821. On March 3, 1873, the name was changed to the Columbian University and on Jan. 23, 1904, to The George Washington University. The old Columbian College was organized and controlled by the Baptist denomination. In 1898 the sectarian control was modified, the president and two thirds of the trustees remaining Baptist. In 1904 with the adoption of its present name the institution became nonsectarian. Its present board of trustees is a self-perpetuating body of twenty-two members, divided into three classes, seven trustees being elected each year. The university has a department of arts and sciences — consisting of the graduate school, the College of Arts and Sciences, the College of Engineering and Mechanic Arts, the College of the Political Sciences, and Teachers College — and professional departments of law, medicine, and dentistry. Also it embraces the National College of Pharmacy and the College of Veterinary Medicine, institutions organized under its charter as separate corporations with independent financial foundations but educationally parts of the university. The endowment of the university has through past administration been greatly impaired, the loss in it being now covered adequately but unproductively by a deed of trust on the medical school and the hospital buildings. The university is therefore to a great extent dependent financially on tuition fees and subscriptions pledged by friends. The instructing staff, 1910-1911, numbered 176, but in many instances members of it give only part time to the university. The students, 1910-1911, were 1277, divided, including 13 duplicates, as follows: Graduate School 54, College of Arts and Sciences 281, College of Engineering and Mechanic Arts 176, College of the Political Sciences 77, Teachers College 93; Depart-

ment of Law 343, Department of Medicine 98, Department of Dentistry 40, National College of Pharmacy 63, College of Veterinary Medicine 65.

**GEORGETOWN COLLEGE, GEORGETOWN, KY** — A coeducational institution established in 1829 under the auspices of the Kentucky Baptist Education Society. Preparatory and collegiate departments are maintained. The entrance requirements are equivalent to some twelve points of high school work. Degrees of Bachelor of Arts and Bachelor of Science are conferred on completion of the requirements, which include at least one year of work in residence. There is a faculty of twenty members in the college.

**GEORGIA, STATE OF** — The southernmost of the original thirteen states. Ratified the Federal constitution in 1788. It is located in the South Atlantic Division, and has a land area of 58,980 square miles. In size, it is nearly equal to the six New England States. For administrative purposes it is divided into 145 counties, and these are in turn divided into cities and school districts. In 1910 Georgia had a population of 2,609,121, with a distribution of 44.4 persons per square mile.

**Educational History** — In laying out the original towns, considerable bodies of land were set aside by the trustees of the colony for the support of church and school. Schools were maintained by the trustees and charitable friends of the colony, at Savannah and elsewhere. In 1754 the crown took over the colony and agreed to continue the "allowance heretofore usually given by the trustees to a Minister and two school-masters." The agreement so made was kept until the Revolution, the only case on record where the Parliament of England supported schools in the colonies. The most notable educational activity in the colony was the orphan house founded in 1739 by the evangelist George Whitefield (*q.v.*), upon which he had expended by 1764 some £12,000 sterling. This institution was in avowed imitation of Francke's orphan house at Halle, and in it were taught such trades as carpentering, weaving, and tailoring.

The Society for the Propagation of the Gospel (*q.v.*) also gave some assistance to schools in the colonial days.

The first educational interest of the state as such was in a system of county academies. The constitution of 1777 provided that "schools shall be erected in each county, and supported

at the general expense of the state as the legislature shall hereafter point out." As soon as the Revolution was ended, the legislature chartered (1783) academies for three of the counties, giving to each a landed endowment, and granted further "one thousand acres of vacant land for erecting free schools" in each of the remaining counties. The "free schools" here contemplated were of the county academy type. In 1792 the land endowment was changed to £1000 worth of confiscated property; a provision which remained in force until 1835.

The county academies were, in 1785, formed into an administrative system under the newly created state university. In 1784 (Feb. 20) a state "college or seminary of learning" had been chartered and endowed with 40,000 acres of land, being thus the first chartered of American state universities (See GEORGIA, UNIVERSITY OF). In 1785 this charter was enlarged so as to include "as parts or members of the university all public schools instituted or to be supported by funds or public moneys." The *Senatus Academicus* of the university was required to advise "not only upon the affairs of the university, but also to remedy the defects and advance the interests of literature through the state in general." In pursuance of this end it should "recommend what kind of schools and academies shall be instituted, agreeably to the constitution, in the several parts of the state, and prescribe what branches of education shall be taught and inculcated"; should "also examine and recommend the instructors to be employed in them, or appoint persons for that purpose." The president of the university was required to visit the schools regularly and "examine into their order and performances." This plan, remarkable both for its inclusiveness and for its centralization of authority, was in these respects never much more than a legislative dream. The university did not begin work until 1800, the county academies were too widely scattered and the frontier spirit of freedom too strong to allow a central body to exercise real control. By 1820 thirty-one academies had been chartered. In 1821 an "academic fund" of \$250,000 was set aside, the income of which should be divided among the counties. The quota of any county should normally go to the county academy, but it might by special enactment be divided among certain authorized academies in the county, or be given to elementary education (poor school fund). The effect of this "academic fund" appears in the fact that during the next ten years more than three times as many academies were chartered (107) as in the preceding forty years; while the next decade (1830-1840) saw this number more than doubled (256). The "academic fund" was in 1837 transferred to the "common school fund," and the chartering of academies shows an immediate decline. Some of these academies from the first had "female departments," and beginning

about 1825 a number of distinctly "female academies" were chartered. In the smaller places, however, coeducation was the rule. A curriculum of 1806, probably typical of the best, included "English, Latin, and Greek, writing, arithmetic, geography, astronomy, mathematics, and Roman antiquities." Later, elementary education received increased attention in the academies, which thus formed until the Civil War the chief dependence of the state for education.

Prior to the Civil War free schooling was for the most part, confined to the poor and given to them as a charity from state and county "poor school funds." In 1817 \$250,000 was set aside by the state "for the future establishment and support of free schools throughout the state." The next year lots 10 and 100 of each "surveyor's district" in about one third of the state were reserved "for the education of poor children." In 1822 the income from these funds was directed towards paying the tuition of any poor child in whatever school he might chance to be. Special schools were neither established nor contemplated. The working of this plan was at no time satisfactory, and many efforts were made to improve it. When the "surplus revenue" was received from Congress in 1836, one third (about \$350,000) was set aside for school purposes, and a committee was appointed to visit the various sections of the country "particularly the New England states" and report a plan of "common schools." As a result there was adopted in 1837 a thorough system of schools, free to all white children and supported from the income of a "common school fund" (of nearly \$1,000,000), this to be supplemented by a county tax (amendment of 1838), if locally desired. Whether the scheme was too radical a step or whether the panic of 1837 was too disastrous, does not now appear; but in 1840 the "common school" system gave place to a renewal of the "poor school fund" plan. This was improved in 1843, 1849, and in 1852.

Parallel with this general state law were to be found various local efforts. Savannah from 1818 and Augusta from 1821 had "free school societies affording education to the children of indigent parents." These were supported in part by state and county funds. Glynn (1823) and Emanuel (1824) counties had free schools for needy children, Gwinnett (1826) "for the education of the youth of the county." McIntosh county in 1830 had a free moving school. The "academy funds" were in several instances used in connection with such free school systems. These local efforts continued more or less sporadically until the permanent establishment of a common school system in 1870.

In 1845 and again in 1856 efforts were made before the legislature to establish a general system of free schools; but not before 1858 was any real progress made. In that year there was elected as governor a man from the plain people

through whose influence the school fund was much enlarged with provision for its further increase, and an annual appropriation of \$100,000 was made "for the education of the children of this state." This marks the disappearance of the word "poor" from his legislative enactments. By this act each county was to adopt its own school plan; and a county tax was authorized. The next year county boards of education were provided to disburse the funds and examine teachers. As a result of these acts a number of counties organized common free school systems. The war of course stopped this development; but the constitutional convention of 1861 added to the general educational provision, which has been in force since 1798, a clause authorizing the General Assembly "to provide for the education of the people." This clause was retained in the constitution of 1865 (contrary to the statement in Barnard's *American Journal*).

Immediately after the war and before the radical Reconstruction was begun, the legislature adopted (1866) an act establishing a "general system of Georgia schools" in which was provided a state "superintendent of public education," free schooling for all white children, local taxation to supplement state funds, and in general, all the machinery for an efficient public school system. The scheme was to go into effect in 1868. Before that time Congress overturned the existing state government, and placed in power the radical reconstructionists. In 1868 the constitutional convention (more than half of whom were Southern whites) adopted without division an explicit provision for "a thorough system of general education to be forever free to all children of the state." For the first time in the state schooling was provided for the negro.

In 1869 the State Teachers' Association was formed, and this body practically outlined the school law of 1870, which was the first public free-school law passed under the new constitution. The new school system did not escape the mismanagement which characterized the reconstruction period, the school funds were diverted and spent, a large debt was contracted, and as a result, the schools were closed during the year 1872. In 1872 the school law was revised and amended, and this law has formed the basis of the present school system for the state. In 1877 another new constitution was adopted, and, in this, still more explicit instructions were laid down with reference to education. New provisions with reference to state and county taxation for schools were inserted, separate schools for the two races were required, the local school systems in existence were legalized, and an additional mandate was laid upon the legislature to provide "a thorough system of common schools," "as nearly uniform as practicable," for the education of the children of the state. Side by side with this general school system, established by

the law of 1870, there has grown up a series of special school systems, regulated and controlled by local laws. Chatham County (in which is Savannah) was the first to have a separate system, followed closely by the city of Columbus, both being created in 1866. In the same year as the new school law, 1870, Atlanta was created a special school system, Richmond and Bibb Counties following in 1872, Glynn County in 1873. Other cities followed, until practically every town of any size has its local system. Local taxation elsewhere practically forbidden, was possible in these local systems and has been the chief incentive to their formation. Some of the best schools of the South are to be found in the counties and cities of Georgia operating under local and independent laws.

In 1887 the school law was revised, and a number of important changes made. The preparation of all questions for teachers' examinations was placed with the State School Commissioner; the election of teachers by county boards was changed so as to give them discretionary power in elections, instead of being required to elect those nominated by the district trustees, the boards of district trustees were abolished, and the county was made the unit in administration. The state appropriations have been gradually increased until now \$2,500,000 is annually disbursed from the state treasury. In 1891 a State Normal School was established by legislative act, and county teachers' institutes were created. In 1903 the State Board of Education was created a State Textbook Commission as well, with power to adopt a uniform series of textbooks for the schools of the state. In 1904 the state constitution was amended so as to make feasible the levying of county and district school taxes, and this permission has been made use of by many of the counties and districts since that time. In 1906 eleven agricultural high schools were established, one in each congressional district, for instruction in agricultural science. In 1906 the school districts were re-created and trustees appointed, and, in 1905, local district taxation for schools was established for the first time.

In 1910 constitutional provision was, for the first time, made for the state support of secondary education. The next year (1911) provision was made for state inspectors of elementary schools; and the state school board was changed from an *ex officio* body of statehouse officers to a body appointed by the governor, while the power of the board was much increased.

**Present School System.** — The school system of Georgia, as at present organized, is as follows: At the head of the system is a State Board of Education and a State Superintendent of Schools. The State Board of Education is a body composed of the Governor, the State Superintendent of Schools, and four others appointed by the Governor. The Governor is president, and the State Superintendent of

Schools is the chief executive officer of the Board. The Board regulates the supervision of all schools in the state, supervises all certification of teachers for all public schools, provides the course of study for all common and high schools receiving state aid, adopts uniform textbooks, and acts as a court of final appeal from the decisions of the state superintendent. Counties, cities, and towns that levy a local tax for schools and maintain a term of eight months are exempt from the provisions of the law requiring uniformity in textbooks. The State Superintendent of Schools is elected by the people for two-year periods and receives a salary of \$3000 a year. He has "a general superintendence of the business relating to the common schools of the state," and is "charged with the administration of the school laws." He prepares blank report forms, visits the different counties, and examines into the administration of the school law, delivers popular addresses in the interests of education, and makes an annual report to the General Assembly. He is also a member of the State Geological Board. There are three state school supervisors appointed by the state Superintendent, who under his direction hold teachers' institutes, grade papers for state licenses, and "aid generally in supervising, systematizing, and improving the schools of the state."

In each county there is a county board of education and a county superintendent of education. The County Board, except in the four special systems of Bibb, Chatham, Richmond, and Glynn, consists of five freeholders appointed by the grand jury of the county, for four-year terms, and removable for cause by the county judge. They receive \$2 per day for their services, and are required to lay off their counties into school districts, to establish at least one school for white and one for colored children in each, to employ the teachers for the schools, to fix the time and length of the school term, and to act as a judicial tribunal for school affairs in the county. The board may also disapprove of any district trustee elected, and order a new election. The county superintendent of education, is chosen by popular election from among the citizens of the county, for a four-year term, and acts *ex officio* as secretary of the board. He acts further as a medium of communication between state and district officers; must visit each school in the county at least once every sixty days; acts as the agent of the county board in purchasing furniture and supplies; makes an annual report to the grand jury and a monthly report to the State Superintendent of Schools; issues certificates to school trustees; and examines teachers for licenses. The minimum salary for this office is \$600 per annum, but the county board may make such additional compensation, "as may be in their judgment proper and just." County boards

may employ him to take the school census, for which he may be paid \$2 a day.

Each county, not under local laws, is divided into school districts of at least sixteen square miles, though smaller districts may be laid off if conditions require it. For each district, three trustees are elected for three-year terms, one each year. In incorporated towns, five trustees are elected for three-year terms. These boards of trustees are to supervise the school operations in their districts, may make recommendations to the county board as to their choice for teachers, and must make an annual report to the county board. In districts which vote a local district tax, the boards of trustees may make all rules and regulations for the government of the schools, may build and equip their schoolhouses, subject to the approval of the county board, and may fix the salaries of their teachers. Any city of over 2000 inhabitants may organize an independent school system and report direct to the State School Commissioner, and any county may be so organized by an act of the General Assembly. Such independent systems make their own course of study, and may by permission of the state board certificate their own teachers.

**School Support.**—The state appropriation constitutes about 65 per cent of the total school revenue for the state, and is apportioned to the counties and local systems on the sole basis of the number of children 6–18 years of age. In each county not operating under special laws, an election to vote a county tax may be called by a petition signed by one fourth of the voters, and a two-thirds majority of those voting enacts the tax. The county board determines the amount, not to exceed five mills. By a similar petition and election, any district may vote a similar district tax, the local board of trustees determining the amount up to five mills. A considerable amount is still contributed from private sources, and in some districts a species of the rate tax is still allowed, by common consent, in the form of a small incidental fee to cover the cost of school supplies, fuel, and janitor service, though pupils who are unable to pay are excused from the fee, and the courts do not recognize the right of the districts to exact the fee.

**Educational Conditions** — Of the population of 1910, 45.1 per cent were negroes and 99 per cent were native born. But three states (Louisiana, Mississippi, and South Carolina) have a larger percentage of negroes in the total population. In one half of the counties the blacks outnumber the whites, and in one fourth of the counties they outnumber the whites two or more to one. The percentage of children, 5–18 years of age, in the total population (33.4 per cent), is high, being larger in but four states, and all of these in the South. While the state has made rapid advances in manufacturing within recent years, it is still

largely an agricultural state, as 84.4 per cent of the total population live in rural districts, and but 11 per cent in cities of over 8000 inhabitants.

In illiteracy, Georgia stood sixth in 1900 in its percentage of the total population, ten years or over, who were illiterate. By race, the state stood third in illiteracy for the negro population and ninth for the white population, and by percentage, 11.9 per cent of the whites and 52.4 per cent of the negroes were illiterate. There was little difference in illiteracy between the sexes. But 1.1 per cent of the total population of the state was of foreign birth.

Outside of the towns and cities, the state has little material equipment for the work of education. The average value of all publicly owned schoolhouses in the state during the last year for which statistics are available was about \$1800. Much of the money for repairs and for new buildings in the rural districts is raised by private subscription. The school term, too, is commonly lengthened by the same means, many communities providing what are called long-term schools by private subscription. The subject matter of instruction embraces agriculture, civil government, and physiology and hygiene, in addition to the common school branches. The State Board of Education adopts a uniform system of textbooks for the schools of the state, but counties, cities, and towns that levy a tax for graded schools and maintain an eight-months school are not required to use the uniform series. Each county board is authorized by law to establish one or more manual labor schools, but such schools must be self-sustaining. As in Alabama, the elementary school system of Georgia is just now being rounded out and classified.

**Teachers and Training** — For the training of future teachers, the state maintains or helps to maintain four institutions, one of which is for the colored race, and there are also three private normal and industrial schools, all of which are for the colored race. Of the state schools, the Georgia Normal and Industrial College for whites at Milledgeville, and the Georgia State Industrial College for negroes at Savannah, are partly normal and partly industrial institutions, and of a type common in the South. The law of the state still authorizes two forms of teachers' contracts, one the usual form by the month, and the other where payments are made to private school teachers who take public school pupils at a certain rate based on enrollment and attendance, and thus conduct a long-term school. The wages of the teachers are low.

**Secondary Education.** — Georgia has its high school system better developed than any of the neighboring Southern States, the state reporting 231 public and 48 private high schools. Of the public high schools, 12 were in cities of 5000 inhabitants or over, while 219 were in smaller places. Six of the total number of

high schools were for the colored race. The state has recently (1910) authorized state aid to high schools, such aid having been expressly forbidden by the Constitution of 1877. With the development of the agricultural and natural resources of the state, and the consequent increase in the amount of money available for education, conditions may be expected to improve very rapidly.

**Higher and Technical Education** — The University of Georgia (*qv*) at Athens, founded in 1784 and opened in 1800; the Georgia State College of Agriculture and Mechanical Arts, also at Athens, and opened in 1872; the Georgia School of Technology, at Atlanta, opened in 1888; and the North Georgia Agricultural College at Dahlonega, opened in 1872, stand at the culmination of the public school system of the state. The Georgia State Industrial College, at Savannah, offers somewhat similar instruction for the colored race. Georgia has a large number of colleges, nearly all denominational, some of them for the negro race, which offer preparatory and collegiate instruction. Few of them have much endowment or high standards. The state also maintains the Georgia Academy for the Blind, at Macon, the Georgia School for the Deaf at Cave Spring, the Georgia Normal and Industrial College for girls, at Milledgeville; and eleven district agricultural schools for the teaching of the elements of agriculture. The Normal and Industrial College is one of a type of institutions found in the South, which offers training to girls along vocational, industrial, normal, and musical and artistic lines.

**GEORGIA, UNIVERSITY OF, ATHENS,**

**GA** — The earliest state university in the United States, chartered in February, 1784, while the University of the state of New York received its charter in May, 1784. By the amended charter of 1785 all public education in Georgia was made a part of the University (see **GEORGIA, STATE OF**). The early studies provided in the University were mainly literary, and only the arts degree was conferred. The land grants made by Congress in 1862 made the establishment of the Georgia State College of Agriculture and the Mechanical Arts and the provision of modern scientific studies possible. In 1867 the Lumpkin Law School was incorporated as a department of the University;

the North Georgia Agricultural College followed in 1872; and in 1873 the Georgia Medical College at Augusta became a department of the University. The following institutions are also branches or departments of the University: Georgia School of Technology at Atlanta, 1885; Georgia Normal and Industrial College for Girls at Milledgeville, 1889; Georgia Industrial School for Colored Youth at Savannah, 1890; and the State Normal School, near Athens, 1895. More recent extensions are the School of Pharmacy, 1903; the Summer School, 1904; Georgia State College of Agriculture; the School of Forestry, 1906; and the School of Education, 1908. Franklin College is the college of arts. The government of the University is in the hands of a Board of Trustees appointed by the Governor. The support comes from state taxation, federal grants, and private gifts. The University campus extends over an area of 132 acres, and the University farm covers 830 acres. The main building equipment comprises fifteen buildings. The admission requirements are fourteen units, four conditions being allowed. The degrees of Bachelor of Arts, Bachelor of Science, Bachelor of Science in Civil Engineering or Agriculture, Bachelor of Law (after a two years' course), are conferred on completion of the appropriate courses. Degrees are also conferred by some of the affiliated institutions, as the North Georgia Agricultural College, the Medical College, the Georgia School of Technology. The enrollment of students at Athens in 1910-11 was 940, distributed as follows: graduate school, 7; college, 180; science and engineering, 176; agriculture, 223; law, 55; pharmacy, 19; summer school, 337. The University at Athens has a faculty of 46 members, of whom 25 are professors and 9 adjunct professors. David Crenshaw Barrow, LL D., is the chancellor.

**GERBERT, or GERBERTUS** — One of the most remarkable scholars of the Middle Ages, and a man who had a marked influence upon mathematical instruction. He was born at or near Aurillac, about 950. Richer, his pupil and friend, to whom we are indebted for most of our knowledge of his life, speaks of him as an Aquitanian, and relates that as a child he entered the monastery of Saint Gérald. Other writers speak of his family as being related to royalty, but in spite of careful research his parentage still remains obscure. He seems to have been a brilliant student, and one of agreeable manner and without forwardness. In 967 Borel, Comte d'Argel, lately become lord of Barcelona, visited Aurillac and saw the youthful Gerbert. The abbot, informed by Borel that Spain at that time had a number of distinguished scholars, confided Gerbert to him in order that the boy might acquire the learning of that country. Borel gave Gerbert into the charge of Hatton, Bishop of Vich, under whom, Richer tells us, "he made rapid progress,

particularly in mathematics." Gerbert remained three years in Barcelona, and in this time he may possibly have learned the Hindu-Arabic numerals (see NOTATION), since he knew something of them later in life. After this sojourn he accompanied Borel and Hatton to Rome, where in 970 he was presented to Pope John XIII. The Pope was so pleased with the young monk's proficiency in music and astronomy that he spoke of him to Otho I, a monarch with great interest in education, although himself illiterate. Through these circumstances and by means of his natural abilities, Gerbert obtained the favor of both Pope and emperor, and in 972, at his request, he was allowed to go to Rheims with the archdeacon Garamnus in order to study logic under this scholar. The diocese of Rheims at that time possessed 700 cures and 23 monasteries, the most important of the latter being that of St Denis. Here it was that Gerbert carried on his later studies, and here he made a brilliant reputation as a teacher. His chief work in the lecture hall was in rhetoric, but he acquired a great renown as an arithmetician from his use of a special form of the abacus (*qv*), a form that may have been invented by him. He also used certain numerals known as the apices (see NOTATION), forms that are often attributed to Boethius (*qv*). He also had a great reputation for his work in astronomy, which subject he taught at Rheims. After a brilliant period of teaching in this monastery he was made abbot at Bobbio (982), one of the most important church positions in Italy, and nine years later (991) he became Archbishop of Rheims. In 998 he became Archbishop of Ravenna, and a year later he was elevated to the papal chair as Sylvester II. He reigned as Pope only four years, dying on May 12, 1003. His mathematical works include a treatise on the abacus, a work *De numerorum divisione*, and a work *De geometria*. D E S

**GERBERT, MARTIN, BARON OF HORN-NAU AND PRINCE-ABBOT OF ST BLAISE** (1720-1793) — One of the most learned and saintly Roman Catholic prelates of the eighteenth century. He was educated at the Jesuit College at Freiburg and in the cloister of St. Blaise and enriched his mind by varied culture and by travels, from which he brought back abundant spoil of Mss from the libraries of Europe. Historical research, especially in

music, was his favorite pursuit. He formed relations with learned societies everywhere, and made many important discoveries in this field. His treatise *De Cantu et Musica* was published in two volumes in 1774 and has ever since formed the basis of all musical scholarship. The *Scriptores Ecclesiastici de Musica Sacra* (1784) created a sensation in the musical world and was of the highest value for the study of music. It was a collection of all the ancient authors who had written upon musical subjects from the third century to the invention of printing and whose works had remained in manuscript and were for the most part unknown. **GERBIER, SIR BALTHAZAR** (?1591–1667)

— Painter, architect, and courtier. He devised schemes for the education of noblemen and gentlemen's sons in an Academy in Bethnal Green. Gerbier was a Dutchman and came to England in 1616 and entered the service of George Villiers, afterwards Duke of Buckingham. In 1631 Gerbier was King Charles I's agent at Brussels and in 1641 Master of the Ceremonies. He issued prospectuses, June 28, 1648, and in 1649 on June 18, August 4, October 31. The prospectus for June 28, 1648, is addressed to "all Fathers of Noble Families and lovers of Virtue," in which he stated he was founding an Academy in which would be taught French, Italian, Spanish, German, and Low Dutch, both ancient and modern histories, jointly with the constitution and government of the most famous empires and estates of the world. Courses were given in experimental Natural Philosophy, mathematics, including arithmetic, bookkeeping "by double parties," geometry, geography, cosmography, perspective, and architecture, practical mathematics, to include fortification, besieging, and defending of places, fireworks, ordering of battalia, and marches of arms; music, playing of all sorts of instruments, dancing, fencing, riding the erect horse, together with the new manner of fighting on horseback. Permission was also to be made for teaching drawing, painting, limning, and carving. Gerbier announced that he was himself preparing treatises for the study of modern languages. He was also prepared to lodge the sons of gentlemen in his own house at Bethnal Green. He thus promises to parents an education for their sons at home in England, similar to what they could get in academies abroad and the avoidance of the "dangers and inconveniences" of education abroad, "in these evil times." In the prospectus of August 4, 1649, Gerbier provides a time-table. The regulations are modeled to some extent on those of Sir Francis Kinaston's (*q v*) *Musaeum Minervae*. On December 21, 1649, he issued a notice that ladies might attend his lectures, and adventurer as he was, he is probably to be

credited with being the first in England to encourage the idea of men and women attending academic lectures together. F. W.

**GERMAN INFLUENCE ON AMERICAN EDUCATION** — German educational ideas and methods have profoundly influenced all parts of the American system of education, but especially its top and its foundation, the university and the elementary school, including the kindergarten, both of which have been either created or fashioned on the model of the corresponding German institutions.

This influence has been exerted through five different channels, which, of course, frequently run into one another and cannot be entirely separated, namely, (a) through the work of German-Americans and of German-American schools; (b) through American students educated in German universities (see *Rep. U. S. Com. Ed.*, 1897–1898, Vol. I, pp. 610–613); (c) through reports on German education published by American and other visitors of German schools; (d) through the study of German pedagogy, psychology, and philosophy on the part of Americans in this country; and (e) through the work of German lecturers brought over either as exchange professors or by invitation of such bodies as the Germanistic Society of America (*q v*).

Of these, the direct influence of German-Americans and of the German-American schools has been comparatively small, certainly not so great as might have been expected, considering the numerical proportion of the German element, which is estimated at about 27 per cent of the total population. The chief reason for this lack of direct influence lies probably in the difference of language, which separated the German-American schools from the main current of national education, and also in the fact that nearly all of these schools were either private or parochial schools. Still a large number of German-American teachers have played an important part in American education. Among these are Franz Daniel Pastorius (1651–1719), the first German teacher in America, the founder of Germantown; Carl Follen (1795–1840), the first professor of the German language in Harvard; Francis Lieber (1800–1872), who introduced gymnastic training into Boston and afterwards became one of the greatest jurists of America, H. E. von Holst, the author of the *Constitutional History of the United States*; William N. Hailmann, superintendent of public schools at La Porte, Ind. (1883–1894), afterwards national superinten-

dent of Indian Schools; and many others. What was perhaps the earliest book of a pedagogical nature to appear in this country was from the pen of a German, Christopher Dock (*qv*), a master of one of the early Pennsylvania schools (See PENNSYLVANIA, STATE OF, PAROCHIAL SCHOOL SYSTEM).

Among the first American students matriculated in German universities were George Tichnor, Edward Everett, George Bancroft, and Joseph G. Cogswell, all of whom studied in the University of Göttingen. Everett was the first American who received a Ph.D. degree from a German university (1819). Previous to this, Benjamin Smith Barton, of Lancaster, Pa., had obtained the degree of Doctor of Medicine from the same university (1799). Bancroft and Cogswell founded (1823) the Round Hill School, near Northampton, Mass., the first school in this country thoroughly impressed with the German ideas. During the remaining part of the nineteenth century and up to the present an increasing number of American students have pursued advanced studies at Göttingen, Berlin, Halle, and later on also at Leipzig, Bonn, Heidelberg, Jena, and other German universities. Hundreds of these have become professors in American colleges and have transplanted German ideas of advanced instruction and German methods of research upon American soil. Through their students in the graduate departments of universities and colleges this influence has been very widely extended. The foundation of Johns Hopkins University in 1876 marks an epoch in American university education. This institution was, in its fundamental ideas, largely modeled on the pattern of the German university, and most of its early professors had been students in Germany (See COLLEGE, AMERICAN, UNIVERSITIES, AMERICAN).

The most important reports on German education which influenced American schools were those of John Griscom (*qv*) (1819), Alexander D. Bache (*qv*), and C. E. Stowe (*qv*) (1833), but particularly that of Victor Cousin (*qv*) (1831), which was translated into English, and published in the United States in 1835. The American publication of Cousin's work proved to be of enormous influence on education in the Middle West. Equally important was the famous *Seventh Annual Report* of Horace Mann (1843), which, among other things, called special attention to the methods of the Prussian normal schools.

The study of German literature and philosophy among English-speaking peoples may largely be traced back to the influence of Coleridge and Carlyle. In America these studies received an impetus through Emerson, Theodore Parker, Margaret Fuller, Frederick H. Hedge, Henry Barnard, William T. Harris, Elizabeth Peabody, Charles De Garmo, and others. Barnard, in his *Journal of Education*, published translations from Karl von Raumer's

*History of Pedagogy*; Harris studied the philosophical system of Hegel and the pedagogical philosophy of Karl Rosenkranz. Miss Peabody became an enthusiastic follower of Froebel and founded (1867) the American Froebel Union; Charles De Garmo, the McMurrays, and others, introduced American teachers to the pedagogy and philosophy of Herbart.

The custom of bringing over German lecturers on educational subjects is of recent origin, so that the results of this activity still lie with the future. Yet an important influence may be expected at least in two directions, namely, towards vocational training, through the work of the Munich school superintendent, Dr. Georg Kerschensteiner, and towards the improvement in teaching modern foreign languages through the inspiration given by Dr. Max Walter, director of the *Musterschule* in Frankfurt a. M. F. M.

See under separate titles for further account of the persons mentioned in this article, esp., PESTALOZZIAN MOVEMENT IN AMERICA, MANUAL LABOR INSTITUTIONS, FELENBERG, FROEBEL, KINDERGARTEN; COLONIAL PERIOD IN AMERICAN EDUCATION; etc.

**GERMAN INFLUENCE ON ENGLISH EDUCATION** — At the time of the Reformation, German influence, commingled with that of Erasmus, Calvin, and Sturm, made a deep and lasting impression upon the course of study in English schools and upon the English idea of the relation between the state and education. Luther's *Schrift an die Rathsherren aller Städte Deutschlands, dass sie Christliche Schulen aufrichten und halten sollen*, written in 1524, had its echo in the preamble to the Chantry Act passed in the first year of King Edward VI (1547), and in the Constitutions and Canons Ecclesiastical of the Church of England, 1603, especially Canons LIX and LXXVII-LXXIX. There are traces of the same influence in English Poor Law administration as early as the reign of Elizabeth and prior to the Poor Law Relief Act of 1601, which first recognized the public obligation to supply elementary education in the case of the children of the destitute poor. In the curriculum of the English Grammar Schools the educational influence of Melancthon (*qv*), combined with that of Maturin Cordier (*qv*) of Geneva, is clear, especially in the emphasis which was laid upon religious instruction as a dominant feature in the course of training.

The influence of Protestant Germany was deepened in English education in the seventeenth century by the study of the works of Comenius (*qv*), and especially of his *Great Didactic* (first published in Latin, 1657), and of the *Januae Linguarum Vestibulum* (English translation, 1647) and *Orbis Pictus* (1657). At the invitation of his friend, Samuel Hartlib, Comenius visited England in 1641, and, if the

disturbed political condition of the country had not prevented it, might well have been engaged to take a leading part in the reorganization of English education. Comenius's work was well known to Milton, and he is referred to in the latter's *Tractate on Education* (1644) as "a person sent hither by some good Providence from a far country to be the occasion and the incitement of great good to this island." The Civil War, however, and the reactionary tendencies of the Restoration period prevented the influence of Comenius from bearing full fruit in the educational life of England.

In the last years of the seventeenth century, 1698-1699, Dr Bray (*qv*) and his associates established a *Society for Propagating Christian Knowledge* (*qv.*), one main purpose of which was "to set up catechetical schools for the education of poor children in reading and writing, and more especially in the principles of the Christian religion." In the movement for the reformation of English morals and for the establishment of charity schools (*qv.*), the influence of the German Pietists was strong. August Hermann Francke (*qv*) was asked to send over two Germans to help in the setting up of Charity Schools, and these two visitors attended a meeting of the Society on May 11, 1699, to give an account of the school which had been erected at Halle by A. H. Francke, who was at the same meeting chosen a corresponding member of the Society.

The educational efforts of John Wesley (1703-1791), especially during the years 1742 onwards, were greatly influenced by what he saw among the Moravians during his visit to Herrnhut in 1738. The Moravian polity, influenced by Pietism (*qv*), made the Orphan House, which aimed at giving a Christian education to boys and girls, an essential part of the organization of the Church. From 1760 Moravian schools in England have exercised a quiet but beneficial influence in English education.

The next great wave of German influence came into English education through S. T. Coleridge, who, in 1830, in his essay on *The Constitution of the Church and State according to the Idea of Each*, echoed the teaching of Fichte (*qv*) that the aim of statesmen should be "to form and train up the people of the country to obedient, free, useful, and organized subjects, citizens and patriots, living to the benefit of the state and prepared to die in its defence." Throughout the great speeches on education made in the English Parliament by Brougham (*qv.*), Roebuck, and others during the years 1833-1835, German precedent for compulsory education was quoted as a convincing proof of the practicability of making elementary instruction obligatory by law. After Coleridge, Thomas Carlyle (*qv*) did much to familiarize the English public with German ideals of state-organized education, especially in *Past and Present* (1843) and in *Latter-Day Pamphlets* (1850). It was, however, through Albert,

the Prince Consort (who married Queen Victoria in 1840), that enlightened German ideas as to the action of the state in public education became most widely extended in England. During the twenty-one years of his residence in England, Prince Albert succeeded, with the help of Lyon Playfair and others, in developing the State Department of Art and Science and in promoting wise extensions of state activity in elementary and technical education.

The success of the Prussian army in the war with Austria in 1866 drew attention to the military and social value of the intelligence and discipline which had been diffused throughout the German people by the elaborate organization of state-aided schools. The impression thus produced upon the public mind was one factor which led to the carrying of the Elementary Education Act in 1870 and to the subsequent adoption in 1876 of the principle of compulsory education (See ENGLAND, EDUCATION IN).

Since that time German influence in English education has been persistent and penetrating. At every point German methods have been investigated and German precedents quoted. Of all English writers, Matthew Arnold (*qv*) was the most successful in attracting the attention of responsible English administrators and statesmen to the value of the German methods of educational organization. Since 1880 German influence has consequently been noteworthy in English policy as regards secondary education, technical instruction, and university development. The latest illustration of the same influence is found in the movement for the enforcement of attendance at continuation schools, part of the Scottish Act of 1908 having been avowedly modeled to some extent on German precedent, and the latter being constantly quoted in favor of the adoption of a similar policy in England.

In four respects German influence has been especially strong in English education: (1) From the Reformation to the present time it has tended to strengthen the view that religious teaching should be part of the regular curriculum of state-aided elementary and secondary schools. (2) Throughout the nineteenth century it has supported the idea that the state should take an effective and, indeed, determinative, part in the regulation of all grades of national education. (3) It has stimulated in the highest degree the scientific study of methods of teaching and of the philosophy of education. (4) It has secured general acceptance for the view that the state can help in developing the economic prosperity of a nation by the systematic encouragement of technical and commercial instruction. **GERMANISTIC SOCIETY OF AMERICA, THE** — Organized in New York City in 1904 to promote the knowledge and study of German civilization in America and of American civilization in Germany, by supporting university instruction in these subjects, by arranging public lectures, by publishing and distributing documents, and by other means adapted to the ends for which the Society is established. In accordance with this program a lectureship on the History of German Civilization has been maintained at Columbia University since 1905, while during the first term of the academic year 1907-1908 a similar course of lectures was delivered at Yale University. Other German scholars and authors invited by the Society to lecture in New York and other cities before colleges and universities and German societies include Professor Friedrich Delitzsch, Berlin; Dr Ludwig Fulda, Berlin; Professor Otto Hoetzsch, Posen; Professor Hermann Anders Krüger, Hanover; Dr Carl Hauptmann, Mittel-Schreiberhau, Professor Max Friedlaender, Berlin, Professor Rudolf Lehmann, Posen; Ernst von Wolzogen, Darmstadt, Professor Wilhelm Paszkowski, Berlin; and Rudolf Herzog, Rheinbreitbach. Similarly a number of American scholars have lectured in Germany under the auspices of the Society and of the Prussian and Saxon Ministries of Public Instruction. In addition a large number of single lectures and courses of lectures on German literature, music, education, art, history, politics, etc., have been provided in New York City (including Brooklyn), both in German and in English. In 1908 the Society inaugurated a series of publications, which include

lectures delivered by Professor John W Burgess, Columbia, on *Germany and the United States*, and on *The German Emperor and the German Government*, and by Dr Carl Hauptmann on *Das Geheimnis der Gestalt*. The publication of a quarterly journal devoted to the interests of the Society and to the promotion of the aims mentioned above is contemplated. The first president of the Society was President Nicholas Murray Butler of Columbia University (1905-1907), who was succeeded by Professor John W Burgess (1907-1909), and Edward D Adams, Esq (1909-1911), donor of the Deutsches Haus at Columbia University and Professor William H Carpenter of Columbia University (1911- ) R. T., Jr.

**GERMANY, EDUCATION IN. — GENERAL CHARACTERISTICS.** — The German educational system, more than that of any other country, has been formed on the one side through the definite plans of the governing body and on the other through the ideas of philosophic thinkers, and has always remained in a condition of progress and development, although it has often been criticized as torpid. There have appeared in this country neither such absolute centralization nor such sudden transformation as in France. The importance of the German educational system rests mainly on the elementary schools, the gymnasiums, and the universities. But besides these many other types of educational and training institutions have been developed and at present are increasing, while influences from abroad are constantly being felt and followed. Multiplicity of types and a variety of finer distinctions between them are promoted by the existence of the German states side by side, for they are entirely independent in their domestic affairs. It is true that the smaller states have frequently followed the example of the largest federal state, Prussia, but generally this has not been done without considerable departures. Hence an understanding of the German system has by no means been acquired after a glance at the Prussian, and there is as little justification for thinking that a knowledge of the Prussian schools of one particular type has been obtained after observation of one individual instance, — a mistake which is easily made by foreign visitors. Even where the regulations are at bottom similar, individual institutions may show considerable divergence from each other according to the personality of the directors and teachers, or their particular tradition, or the spirit of the locality and its people. At present also the bodies controlling education are explicitly favoring greater independence in the indi-

vidual schools. The period of greatest uniformity has passed for Germany, while in France this ideal is still maintained to a large extent. The establishment of uniform types of schools is never prompted merely by the desire for control; rather is this based on a belief that the ideal has been discovered and a desire that this ideal should be put into practice everywhere. Owing both to external (economic and other) and internal reasons some hesitation is apparent in relation to the new movement. Foresight and discretion are particularly necessary in the face of the ever increasing clamor which with passionate excitement demands the complete overthrow of the present organization. Further, the feeling that the youth of the nation should not be lightheartedly made the subject of experimentation must meet with approval. Moreover it is an undeniable fact that Germany owes the importance which she has gained in recent times in part to the character of her educational system. Not rigidity, but flexibility; not lighthearted destruction, but thoughtful reorganization, these may be said to characterize the fundamental attitude of educational administration in Germany.

**HISTORY** — While a correct appreciation of the educational system of the present is impossible without a knowledge of its history, but the briefest outline will be given here with reference to the titles under which the subjects are discussed. In the Middle Ages education and culture in Germany, as in all other European countries, lay in the hands of the Church; this period is described under Middle Ages and the various topics to which cross reference is there made. This education was accompanied in the case of the upper classes of society by another training for physical and military ability and excellence, and at the height of the medieval period the ideal of chivalric training was introduced from France, an aim which included polite conduct, feeling for the social accomplishments, an understanding of poetry and music. (See CHIVALRIC EDUCATION.) For the people as a whole, that is the lower class of society, beyond the general religious and moral influence, nothing was done (See, however, the CHARLEMAGNE AND EDUCATION for the period of revival which included the Germans.) For the simplest needs of economic life writing and ciphering were taught in private schools, while on the other side out of a number of the most important ecclesiastical institutions of learning there grew the universities which, however, bore no national character, but reproduced a fairly similar type in France, Italy, Spain, England, and Germany, and in consequence of the universal prevalence of Latin were visited by members of the different nations. (See below GERMAN UNIVERSITIES.)

For the close of the Middle Ages the discussions under SCHOLASTICISM, RENAISSANCE PERIOD, HUMANITIES, CICERONIANISM, and

especially the REFORMATION AND EDUCATION relate to Germany. Also the history of Universities (*qv*) is closely related to the Teutonic peoples. The development during the Reformation is further discussed under Luther, Melancthon, Sturm, and other leaders.

An opportunity for the founding of a large number of important schools in the century of the Reformation was afforded by the dissolution of wealthy monasteries by the authorities which had adopted Protestantism. Several of the schools organized at that period attained considerable reputation, educated men of renown, and in a modified form are still in existence; examples are the *Klosterschulen* (see *Cloister Schools*) in Wurtemberg and the *Fürstenschulen* (*qv*) in Saxony. At the same period, too, the ruling princes began to undertake the task of educating their subjects, not as might be thought merely from ideal motives, but with the not unpraiseworthy object of insuring for their countries capable officers, judges, preachers, and teachers. Hence in the course of the sixteenth and seventeenth centuries there were issued in the different states of the Empire well-planned school ordinances; in other words, a definite, universal organization of the school system, including courses of study and instructions on method, took place. Saxony, Brunswick, Wurtemberg, and Saxe-Gotha deserve special mention here. (See ERNEST THE PIOUS, GOTHA, SCHOOL REFORM IN.) The amount of industry applied by teacher and taught in schools of that period to the attainment of the established humanistic aim, the number of periods, and the extent of the reading, can cause nothing but astonishment. The educational actions in Catholic Germany during this period is also treated under JESUS, SOCIETY OF, EDUCATIONAL WORK OF, and related topics.

In the seventeenth century the eccentric Wolfgang Ratke (*qv*) and the broad-minded and keen-sighted J. Amos Comenius (*qv*), who proposed entirely new ideas and plans for the aims and methods of instruction, restored the vernacular to its more important place, sought more correct, psychological foundations, made learning easier for the young, and hoped with some assurance to help towards a humanity that would be more valuable. These practical efforts were influential only for a brief period and over a small section of the German schools.

From the humanistic pedantry a departure was made towards the end of the seventeenth century in the direction of versatility and practicality of social requirements by the educational system of the so-called *Ritterakademien*, that is, institutions for the sons of the nobility. (See ACADEMIES, COURTLY.) Here instruction was given in several modern languages as well as a variety of recent sciences and many chivalric and practical accomplishments, generally in a cursory and superficial manner.

The majority of these institutions, however, did not enjoy a long existence. But their aims were partially and gradually adopted in the other institutions for higher education, while even the educational organizations of the Pietists (*qv*) (c 1700), especially the school system established at Halle by A H Francke (*qv*), now included a variety of *real* knowledge, offered an opportunity for learning different types of manual and industrial occupations, introduced easier methods to facilitate the learning of Latin, made room for exercises in the vernacular, and, as is to be expected, made religious and moral education the main object. From this point *Real* schools were developed since about the middle of the eighteenth century, the earliest of which in a modified and improved form still continues to exist in Berlin. (See HECKER) The pedagogy of the Pietists equally promoted opinion in favor of the right of the lower classes to education.

After compulsory school attendance had already been introduced in the seventeenth century in some of the small Thuringian states, as, *eg* in Saxe-Gotha, such compulsion was definitely imposed from 1713 in the rising state of Prussia by the energetic, yet reckless king, Frederick William I. Under his greater successor, Frederick the Great (*qv*), the elementary school made hardly any progress. There was a feeling for a long time that duties of an elementary school teacher should be intrusted to anybody of the most modest personal education, such as artisans, or non-commissioned military officers, while instruction was limited to the elements of reading, writing, and arithmetic and questions on the Catechism. The view that religious knowledge or even only verbal formulæ are a guarantee for Christian feeling and God-fearing conduct was only gradually superseded, or perhaps has not yet altogether disappeared. The first actual normal school was established towards the end of the reign of Frederick the Great at Halberstadt in 1778, and that through the efforts of a private person, the noble philanthropist and friend of youth, Eberhard von Rochow (*qv*), who found a supporter of his principles in the Minister of State, Freiherr von Zedlitz (*qv*), whose highly meritorious activity was devoted to the perfection, internally and externally, of the whole public educational system. Both men were influenced by the new spirit of Philanthropism (*qv*) which in its turn had partly been aroused by Rousseau (*qv*), but in several points had deviated widely from his views. With a new view of the aims and means of education not only the founder of the movement, J B Basedow (*qv*), established an institution at Dessau, styled the *Philanthropinum* (1774), but a number of similar institutions followed, and there was no lack of active followers (See CAMPE, SALZMANN, etc.). With Rousseau they shared the belief in the original goodness of human

nature; they desired to subordinate the importance of instruction to that of an education for other valuable qualities, recognized the natural rights of youth, and hoped to dispense almost entirely with pressure, compulsion, and punishments. In the spirit of the time they saw in happiness the true end of all human education. Quite in opposition to Rousseau, however, they always thought of the ability of their pupils in reference to the enlarged society, and social usefulness was to be combined with happiness. Throughout they also stood for authority and obedience. But while they turned all learning to play, swept away all real difficulties from before their pupils, were satisfied with all kinds of superficial knowledge, were willing to stimulate by a system of external rewards, they in no way promoted true character-formation, and called out the strongest opposition, while their institutions only attained a slight importance. It must at once be said, however, that several of their principles have recently again come to the front and receive wide recognition.

The most determined opponents of the Philanthropists were the representatives of the New Humanism, who then won a decisive influence over the organization of higher education, which continued for a long time (See NEO-HUMANISM). The earliest leaders in this movement, including, from about 1730 on, J. M. Gesner, Ernesti, Heyne (*qv*), also had their broad pedagogic convictions and desired to win over the student body by beauty of content in the subject-matter, that is, essentially the classical antiquities. From this time on, it remained the program of the new humanistic educators to inspire enthusiasm for the language, literature, thought, and character of antiquity, and to promote the moral development of their pupils by the study of a nobler human type. In this attitude the great poets, as for example, Herder (*qv*), were either in agreement with or even anticipated the philologists, as Fr August Wolf or Friedr Thiersch. Influential statesmen, too, adopted the same views, and a particular instance is William von Humboldt (*qv*), who about 1810 directed the Prussian educational system, and together with several important councillors exercised the decisive influence in the organization of the gymnasiums. And yet the philologically trained teachers, to whom instruction in the classics was intrusted, failed in the subsequent period to arouse that expected enthusiasm, since they restricted their pupils too much to the linguistic difficulties. Nor could the view that the ancients presented the highest type of humanity be maintained according to the modern conception of Greek and Roman antiquity.

Equally significant was the influence exercised on lower education in Germany at about this time (1800) by the great-hearted Swiss, Pestalozzi (*qv*). His efforts, although applied

only in small private undertakings, were very soon recognized and fully appreciated by representatives of the Prussian state and were adopted as the standard for the internal organization of their elementary schools. With this there began not only a new and better period for these schools, not only were their services increasingly valuable, not only did the new and idealistic class of elementary school teachers arise in the one state, but this state, Prussia, where at the same time that new class of high school teachers had arisen, acquired a position as leader and guide of Germany, while Germany itself in the subsequent period stood out as the country of the most intensive pedagogical interests and the most consistent educational organization. Many differences remained in the last few centuries between North and South, and particularly between Protestant and Catholic territories, but in the educational sphere there gradually appeared a satisfactory assimilation. The Roman Catholic Church, indeed, has never ceased to claim all school education for herself and her ministers, and the German governments have never ceased to admit to the Christian churches a right to share within well-defined limits in the supervision of the schools and to utilize the assistance of their representatives. But on the whole the schools have more and more become a matter for the state alone, even in cases where the maintenance and direct support were undertaken by individual communities.

The external organization of the lower as well as the higher schools (the latter being styled in South Germany "middle schools" with reference to the Universities which are the real "high schools") continued in the course of the nineteenth century to be carried on predominantly on the plan that typical forms must so far as possible be made universally binding, with the result that flexibility in the individual schools, teachers, and even pupils was temporarily checked. It is noticeable, however, how this whole tendency is gradually giving place since the last century to another which is opposed to it. The number of educators who took part in perfecting the system has always been great at this period and the investigation for better methods has scarcely ceased for a single moment. The strongest impulse in this direction was afforded by Herbart's (*q.v.*) pedagogy (first published in 1806), even though his psychological principles have been shattered since then and their too mechanical formulation, which was the work of his disciples, especially Ziller (*q.v.*), is at present being attacked or rejected on all sides. But the careful research into the teaching and learning processes which since that time is being pursued with still greater psychological thoroughness is the undoubted contribution of this great educator.

So far as the further development of the

external organization is concerned the elementary schools with universal compulsory attendance have not only been increased from decade to decade, but have been more carefully articulated into classes, the hitherto poor material conditions of the teachers have been improved, the training of teachers in numerous normal schools and the preparatory institutions preceding them have been perfected, and a large variety of schools for pupils deficient in some personal equipment have been erected. New cultural subjects have been added to the simple, traditional elements in the curriculum of the ordinary elementary schools, and in recent years the care for the further education of pupils from the age of fourteen, the leaving age for the elementary school, up to sixteen or eighteen, is a matter of considerable discussion and experimentation. Attendance at continuation schools has already been made compulsory in many places, since intellectual and moral neglect, particularly at this age, is fraught with much danger to national life.

For higher education it was particularly significant that the transition from the gymnasium, which had gradually increased to nine classes, to the university was since the end of the eighteenth century (1788 in Prussia) made dependent on an exacting leaving examination (*Maturitätsprüfung*) and has so remained. Further, there was introduced a difficult examination *pro facultate docendi* (1810 in Prussia) which called into existence a well-defined and trustworthy profession of high school teachers. For the supervision of the teachers and administration of school affairs the government bodies established their own, purely state authorities, as for example the *Ober-Schul-Kollegium*, since 1825 *Provinzial-Schul-Kollegien* (Provincial School Boards) with a comparative amount of independence under the Minister of Instruction. Lastly, certain state privileges, especially the right to one-year service in the army (*einjähriger Militärdienst*), were attached to attendance at certain types of the higher schools. That this last provision contributed largely to uplift general education in the nation is undeniable. It embodies, moreover, a democratic principle, since no distinction of rank or wealth is considered in connection with that privilege, which may be attained by any person through individual merit.

The curriculum, the selection of subjects, the amount of time to be devoted to each in each grade, the regulation for the decisive examinations, have all naturally been frequently revised and altered in the course of time, as changes in the sciences, cultural life, and needs of the time demanded. The last regulation of the courses of study in Prussia dates from 1901. The other German states approximate Prussia in their organization. A controversy extending over several decades centered round the relation of the *Real* schools (that is, schools

with a modern curriculum, modern languages, natural sciences, etc.) to the schools which had their origin in the humanistic period, the *gymnasiums*; although these have in the course of time adopted subjects of more modern content, they are particularly marked by their serious study of Greek as well as Latin, having recently dropped the early rhetorical-stylistic aim of the study of Latin. *Real* institutions, with an equally long curriculum of nine years, were first recognized in Prussia as *Realschulen*. *I. Ordnung*, or *Realgymnasien*. Since 1901 the *Gymnasium*, the *Realgymnasium*, and the *Oberrealschule*, with a Latinless nine-year course, receive fundamentally the same recognition. All these types of schools are regarded as general educational institutions rather than as preparatory schools for any special professional course, and the ever-increasing simpler *Realschulen*, with a six-year course for pupils between nine and fifteen, show the same tendency. It is especially difficult for Germans to think of any educational ideal that is not general and valuable in itself. The utilitarian standpoint meets with only slight recognition anywhere. Hence the formal side of education is regarded as more important than the material equipment for life, while linguistic and grammatical instruction has ceased to be regarded as the sole means for developing the powers of the pupils.

All the higher schools in common pursue with the same objects the study of German (linguistic and literary) and history, while religious instruction is everywhere obligatory. It is demanded in certain quarters that the last should be left to the religious corporations, but the feeling neither of the authorities nor of the teachers is favorable to such a view.

The multiplicity of institutions for instruction and education has increased rapidly in the last decade. The increasingly popular *Reform Schools*, with the postponement of Latin by several years, are only one type. Although coeducation of boys and girls has up to the present not been introduced in most German states, the question of an equal and comprehensive education of the female youth has been seriously discussed and curricula and courses of study have recently been prepared to meet the situation, so that this side of national education seems to have a brilliant future. Another entirely recent tendency is the reestablishment of boarding schools (*Internate, Aluminate*) to be connected with the higher schools, or at least to adopt their curricula and to bear a different character from the earlier boarding schools of an institutional character or the French *lycées*. Most of these institutions up to the present are private undertakings. But all private establishments for education and instruction are under state supervision. The idea of national education must outweigh that of individual education. Individual powers must be developed, but at the same time

altogether in the interests of the nation as a whole.

And nationalism no longer means the obstinate and unquestioning acceptance of traditional peculiarities. Attention is in recent years being frequently directed to foreign countries and the good points in England and America in particular are studied with a view to some extent to their adoption. Thus some experiments have been made in self-government of pupils. A wider power of election is to be permitted to students, at any rate in the upper classes of the higher schools. By the side of gymnastics, which have long ago found a home in Germany, athletics and manual instruction have been increasing. But caution and discretion in the recognition and adoption of new ideas remains the principle with educational authorities in Germany. Hence they have rarely been compelled to retrace their steps.

There has been no lack of alternation between more liberal and more conservative points of view in the last century. At times some very reactionary measures were in force, as in 1850, for the training of elementary school teachers, while at the present moment from the socialistic standpoint very revolutionary demands are being made. Hence the proposal for a uniform school (*Einheitsschule*), with one and the same foundation equally obligatory on all children of the nation, and the free access to all educational institutions for the able,—demands against which strong reasons have been brought. On the other side an attack is made on class instruction which favors only the mediocre, and special schools are now and then demanded for the specially gifted in order to create a national *élite*.

To hold that the German system is at a standstill, or to form the idea of a rigid organism from isolated impressions or exaggerated judgments, it must again be emphasized, would be particularly unjustifiable. It is merely that the present advance is less noisy than elsewhere. The protests against present conditions, which at the moment are raised excitedly in certain quarters and especially in the daily press, are going too far. With unfounded optimism there is talk of the value of unchecked, unregulated development of the immature person, while the effect of the present system is regarded with unjustified pessimism. Confidence in these schools, whose value was previously accepted without question, has disappeared because families were too long kept at a distance from them, and the establishment of confidential relations between teachers, parents, and scholars forms one of the greatest tasks of the future. On the other hand criticism is frequently due to the subjective instability and nervous discontent of educated people of to-day, and serious charges are brought against present education in the family. But each individual thinks that he ought to judge of the

scope of education on a basis of disposition, casual experience, and ideas of the moment

It must, however, be recognized that the task of the future is to provide for the introduction of the field of educational science more generally in the highest educational institutions, the training grounds for the most intensive thinking (See EDUCATION, STUDY OF.) At the same time it is regarded as an equally important need of the educational system to place a professional expert at the head of the whole department which up to the present has been under a Minister merely as one section of his work. But that desires are unfulfilled and that important demands for the future remain, is not a sign of an actual standstill. The great problem of education is always unending and ever gives rise to new questions. That the highest object must under all circumstances be the training of the will is self-evident. But by which system this can best be attained may be left as a subject of competition between the nations

W. M.

**PRESENT SYSTEM.**—As in America, the control of education is constitutionally in the hands of the individual states and is almost entirely removed from the imperial or federal government. The Imperial Chancellor, as representative of the Empire, has only the right of defining the qualifications for the privilege of the one-year service in the army and to bestow to individual schools the right of granting such certificates. For this purpose he is supported by the Imperial School Commission, consisting of about seven members as representatives of different states, and holding a short business meeting usually once a year. Its functions are inconsiderable. The Cadet Corps, which always include a higher school, are under the control of the Emperor as supreme head in military affairs. Thus there is no uniform and unifying imperial authority in German school affairs, and the German educational system is far more varied than appears to a foreigner on a brief visit. The extent of this diversity cannot be wholly presented in this account, which will be devoted primarily to a survey in outline of the school system of the largest federal state, Prussia, and only incidentally to that of other states. Further, Germany does not possess a bureau of information such as the United States Bureau of Education, and it is difficult or even impossible to afford a complete description of the present situation.

While in America there is an educational ladder leading directly from the primary school to the university, no German state has a uniform school system in this sense. On the contrary, two systems must be constantly distinguished, the lower or elementary school system and the higher school system. A transference from one to the other is only possible at one point, viz. after the third or fourth school year. All other types of schools or curricula

are connected more or less closely with these two.

**Legislative Principles.**—As will have been noticed above an imperial educational code does not exist, although the Imperial Law on Child Labor in industrial occupations, March 30, 1903, refers indirectly to education. In addition there are agreements between the federal states for the mutual recognition of examinations, particularly the *Abiturentenexamen* (q.v.) for entrance to the universities. These agreements, which have been entered into by a majority of the states, have at any rate in higher education as unifying an effect as imperial laws, much in the same way as the College Entrance Requirements Board in America.

In the individual states education is regulated either through a comprehensive education code (*Schulgesetz*), as in Saxony and Württemberg, in which case the lower and higher systems are generally treated in separate laws and occasionally only one system is dealt with uniformly; or the most important sections are embodied in special laws while the rest is supplemented by the government through ordinances, as particularly in Prussia. But with the rapid and progressive development of Germany, even where uniform educational laws exist, special laws and various ordinances are necessary to adapt the school system to the changing conditions. Elementary education is based on laws more than higher education, which more frequently, and especially in Prussia, is regulated by ordinances. The following questions are the subjects of legislative enactment in almost all the states, the training, appointment, and conditions of service of the teachers, their pay, pensions, and provision for their dependents, the maintenance of schools, school inspection and attendance, as well as the denominational organization of schools.

Prussia has no school code. The legislative foundations of her school system, apart from a few earlier regulations for individual sections of the kingdom, are contained in Articles 20-25 of the Constitution of January 31, 1850, which run as follows:—

(20) Knowledge and its dissemination are free. (21) Satisfactory provision for the education of youth shall be made through public schools. Parents and their representatives must not allow their children or wards to be without such instruction as is prescribed for the public elementary schools. (22) Every one is free to give instruction and establish educational institutions, provided he has proved his moral, intellectual and professional fitness to the proper state authorities. (23) All public and private educational institutions are subject to the inspection of authorities appointed by the state. Public teachers have the rights and duties of civil servants. (24) In the organization of public elementary schools denominational conditions must be considered so far as possible. Religious instruction in the elementary schools is under the direction of the religious corporations concerned. The management of the external affairs of the public schools is in the hands of the community. The state with the legally regulated participation of the communities appoints teachers from a list of suitable candidates. (25) Funds for the erection, maintenance, and extension of public schools are raised by the communities, and where inability to do so is proved the state may give supplementary aid. The duties of third parties based on special titles remain as before. The state guarantees the teachers a fixed income according to local circumstances. Instruction in public elementary schools is free.

In addition the *Law for the Maintenance of Public Elementary Schools of July 28, 1906*, which includes far more than the title implies, is of importance. Its contents are as follows: (1) Maintenance of schools. (2) Distribution of the cost of elementary schools; maintenance of the schoolhouse; building fund; state support. (3) School property; aid from other sources. (4) Denominational conditions. (5) Administration of elementary school affairs and appointment of teachers. (For the foreign observer sections (4) and (5) are particularly noteworthy.)

Higher education in Prussia is regulated by ordinances or decrees of the Minister or through the supreme decree of the King, while Saxony, for example, has a law also for higher education. (See Lexis, Vol III, p 65; Von Bremen; Morsch.)

**Administration of Education — Central Authorities** — The supreme direction of the internal organization of the schools is in all the states in the hands of state authorities; in Prussia this is provided by Article 23 of the Constitution mentioned above. This power no longer rests as previously with the church, nor, as is general in America, with the local communities. In no state has there yet been developed a central authority whose only concern is school matters. Generally public worship, occasionally a still wider sphere of duties, as, for example, justice in Baden, are under the charge of the same minister; sometimes, as in Hesse, education falls to the share of the Minister of the Interior; a simpler organization is, of course, possible in the smaller states (Hesse has a little over one million population).

The highest authority in Prussia is the Ministry for Public Worship and Education; in Bavaria the Ministry of the Interior for Public Worship and Education; in Württemberg the Department for Ecclesiastical and School Affairs. When the Prussian ministry became independent in 1817, it was still quite possible to supervise the whole field assigned to it. This is no longer possible at present, and since 1911 the Department for Public Health has become a separate body, while the demand for a separate Ministry for Education is constantly becoming stronger. At the head of this office stands the Minister, usually called *Kultusminister*, who is supported by the Under-Secretary as his deputy. The ministry is divided into three departments: (1) Department for ecclesiastical affairs. (2) First department for education (higher and girls' schools). (3) Second department for education (elementary schools). A ministerial director stands at the head of each department. Further there are attached to the office from thirty to thirty-five special councillors and from ten to fifteen assistants. The majority of these officials so far, always including the Minister himself, are jurists or administrative officials. The organization in the other states is much simpler. In several of these, as

in Bavaria and Baden, almost all the councillors are jurists. In addition to the routine administrative duties various conferences take place in the ministry, at which questions are determined not by majority vote, but by the decision of the presiding official. Responsibility, however, is formally borne by the Minister, to whose notice important matters are accordingly brought for his personal decision. Since the Minister cannot supervise the details of his wide field, and frequently has not the necessary acquaintance with persons or the professional knowledge, an extraordinarily wide influence is often exercised by the experienced directors, although the scope of their duties is entirely dependent on the will of the Minister. As an instance may be mentioned the late Fr Althoff (*q v*). Where wider changes are contemplated, the Minister summons a consultative conference to which leaders in all walks of life are invited. Such conferences, for example, took place in 1907 on the reform of the education of girls, as well as in 1890 and 1900 on the reform of higher education.

**Intermediate Authorities** — In the larger German states there are between the central board and the individual schools state intermediate boards, which, although differing everywhere in composition and functions, always have the constitution of boards. Examples of these are in Bavaria the Supreme School Council (*Oberste Schulrat*), in Württemberg the Superior School Council (*Oberschulrat*), in Prussia the Provincial School Boards (*Provinzial-Schulkollegium*). As a rule the members are not elected, but appointed by the central authority, and number variously from five to ten or more. The composition of these boards shows great variety. In Bavaria the board includes two university professors, two professors of technical high schools, five directors of classical gymnasiums, two directors of realgymnasiums, a rector of a real-school, one superior medical councillor. Baden shows a similar constitution. In the free town of Hamburg, which in other ways also possesses a very peculiar school organization, there are lay representatives on this board as well as on the communal education committees. But in Hesse and, particularly, in Prussia, neither university professors nor laymen nor practical schoolmen sit on this board, although a number of members have been in the teaching profession. The sphere of duties of these authorities is as varied as their composition. In Bavaria the Superior School Council has only the management of the internal affairs of the higher schools, while everything of an external character comes under the control of the county administration. In Württemberg only the higher schools are under the intermediate board, while elementary education is administered by the ecclesiastical authorities. In Baden the Superior School Council has charge of both higher and elementary education, including the administration of external as well

## GERMANY

as internal affairs. In these states the intermediate authorities are in intimate relations with the ministry, and with the exception of Bavaria a number of the members belong to both boards. Decisions are reached in Baden and Württemberg by resolution of the intermediate authority, but are subject to the decision of the Minister.

The intermediate authorities in Prussia are organized on a different plan. They are entirely separated from the central board, and between individual institutions and the central authority, the Minister, there are no direct business relations. On the whole, their organization follows that for the administration of internal affairs. The Prussian monarchy is divided into twelve provinces, each under a president. Each province is subdivided into from two to six counties under a county president; the office which administers these districts is known as the County Government (*Regierung*). The county is further divided into town communities, under a mayor, and districts under a chairman (*Landrat*); these districts are again made up of rural communities under an overseer, and estates also under a similar official. The duties of intermediate authorities for lower or public elementary education are undertaken by authorities for internal administration, that is, the County Government (*Regierung*), a department of which is devoted to ecclesiastical and educational affairs. The County Government has the supervision of all school activities, while external administration falls to the share of the community authorities with the approval and confirmation of the county government. The officials of the County Government for the inspection of elementary schools are the District School Inspectors (*Kreisschulinspektoren*), the majority of whom up to the present are clerics primarily and exercise their inspectorial duties incidentally, although the number of definitely professional inspectors is gradually increasing, especially in the towns. Under the District School Inspector stands the Local School Inspector (*Ortsschulinspektor*), an office usually exercised by the pastor or priest of the place, or by the principal for his own school. The principal is the director of the individual schools, in so far as they consist of several classes, and under him are the teachers.

The intermediate authorities in Prussia for higher education, including also normal schools and preparatory training institutions, and, in Berlin only, the elementary schools, are the Provincial School Boards already mentioned, of which there are twelve, one for each province. They are presided over by the Chief President of the respective provinces, who is assisted by a varying number of councillors who have been in the teaching profession. These officials exercise the inspection of higher schools, which are occasionally visited also by ministerial councillors. On the whole, however, the super-

## GERMANY

vision of higher schools is of little value, and inspections take place comparatively rarely, with the result that each school enjoys a great deal of freedom. The duties of the Provincial School Boards are described as follows by Morsch (p. 343), and include:—

(1) All matters bearing on the educational aim of the institutions, (2) the examination of organizations and statutes of schools and educational institutions, (3) the examination of new and the revision and confirmation of already existing ordinances and regulations no less than the provision of suitable recommendations for the removal of abuses and defects which have crept into any educational or school system, (4) examination of school textbooks in use, the decision as to which are to be dispensed with or introduced with the previous approval of the superior ministry, (5) examination of new textbooks, (6) another and more influential means of school inspection is the *Abiturienten-Examen*, at which a commissioner from the Provincial School Board is generally present, (7) the appointment of commissioners to hold the *Abiturienten-Examen*, and inquiry into the transactions of the examination commission in the schools, (8) the supervision, direction, and inspection of schools which lead to the universities, (9) the appointment, promotion, discipline, suspension, and dismissal of teachers in these institutions.

Further to these boards is assigned the supervision of all the external administration, the finances and budget, which in schools maintained by communities are administered locally. Each higher school is administered by a Director, who is assisted by the *Oberlehrer*. The private higher schools, of which there are only a few, are subject to state supervision equally with the public schools.

All these above-mentioned authorities are state officials. In addition there are local or communal bodies, parts of the local administration of communities. Here the multiplicity of deputations, commissions, governing boards, councils, committees, etc., is so great, and their constitution so diversified and frequently so complicated, that any attempt to describe them would be futile, even if the material were available. In general it may be said that only the external administration is the business of the community, such as the erection, equipment, and superintendence of buildings, the sanitary arrangements, financial management, rarely the questions of discipline in the schools, although all these activities are always subject to the approval of the superior state boards. The most important right of the Prussian community is the selection and nomination of the whole teaching body, but here, too, the appointment of every teacher must be confirmed by the state. Towns with larger systems appoint a school superintendent as a professional adviser. This office will increase in importance with the rapid growth of German towns, and the significance which such a position can attain in the hands of an energetic man is shown by the example of Kerschesteiner in Munich. The local bodies do not have the rights of supervisors over teachers and school directors. The higher institutions of learning maintained by the state, of which there are quite a number, are naturally not subject to local control.

**Teachers and Conditions of Service.**—Teachers, whether male or female, whether in

## GERMANY

state or communal schools, have in Germany the position and character of civil servants, whose rights and duties are definitely laid down by general service regulations. Accordingly, they receive their appointments only on the basis of the state-regulated preparation, of which evidence must be given by a state examination (towns have not the right to hold examinations); they have a definite career, definite titles which express their duties or position within the official organism; their position is for life and not terminable by notice, they receive a definite, annually increasing salary; they are entitled by law to a definite pension and to provision for their dependents on their death. The titles and career of teachers in Prussian elementary schools are as follows: immediately on their appointment they are called Teachers, if they have charge of a small school of one or two grades, Principal Teachers, on appointment after the appropriate examination to the direction of a larger elementary school, they are called *Rektor*; finally they can become District School Inspectors. Up to the present female teachers do not advance to higher positions. In the higher schools after the state examination during the period of preparation the title is Candidate for Higher School Appointment, between the period of preparation and appointment they are known as assistant teachers (*Wissenschaftlicher Hilfslehrer*), in the nineties this period was quite long, often up to ten years, but in recent years appointment has followed immediately after the preparatory period as a general rule; after appointment they are called Teachers (*Oberlehrer*), of whom the older members receive the title of Professor, which, however, does not carry with it any other duty or a higher salary. The teacher may rise to the principalship of a higher school with the title of Director. Further they can become Provincial School Councillors, or Special Councillors in the Ministry. A change of career, which is so frequent among teachers in America, is very rare in Germany. This is due to the many rights which the official has and acquires, as well as to the exclusive and specialized preparation for every profession.

Every official may resign his position, but surrenders all the rights which go with it. No official may be given notice, dismissed, or retired on a pension except after a disciplinary inquiry. Disciplinary courts of first instance are the direct superior authorities for officials of the middle class, including the *Oberlehrer*, while for the higher officials, including directors, there is a special court in Berlin; neither of these are the ordinary courts. When proceedings are brought against an official merely for a breach of duty, in so far as it does not trespass the penal code and is only subject to the superior authorities, the case is withdrawn from the ordinary courts.

The income of officials consists usually of several items. The fixed minimum and the

## GERMANY

increments make up the salary proper; to these must be added the compensation for rent, which varies with the cost of living in different places, and occasionally local additions. The officials move up automatically on the salary scale according to years of service. The salary of elementary school teachers is given in the following table (4 20 M = 1 dollar):—

	INCREMENTS AFTER YEARS OF SERVICE									
	After	7	10	13	16	19	22	25	28	31
Minimum Salary										
1400 M		200	200	250	250	200	200	200	200	200
Total salary	1600	1800	2050	2300	2500	2700	2900	3100	3300	

The compensation for rent, which is additional, amounts to from 200 to 800 M, and the local additions, in towns of over 10,000 population, up to 900 M, so that the highest possible income is 5000 M. Female teachers receive a somewhat lower, middle school teachers a somewhat higher salary. The salary of principals consists of the same minimum as that of teachers, *i. e.* 1400 M, to which is added from 500 to 1000 M more in virtue of his position (*Amuszulage*), and a compensation for rent which is more by 25 per cent than that of teachers, *viz.* 250–1000 M. And finally the salaries of District School Inspectors amount to from 3000 to 7200 M, which may be reached in six stages of 700 M each. The compensation for rent is from 560 to 1200 M. The compensation for rent varies with the cost of living in different towns. In Prussia the localities are by law divided into five classes (A to E). To class E belong those places where the cost of living is lowest, so that the rent indemnity is lowest there. Class A stands at the opposite extreme. The rent indemnity is thus a means which, keeping the minimum salary everywhere at the same level, seeks to adapt the total amount of income to local circumstances.

The salary of teachers in higher schools (*Oberlehrer*) is indicated in the following table:

Salary initial	after	3	6	9	12	15	21
	years of service						
2700 M	.	3400	4100	4800	5400	6000	7200

To this from 560 to 1300 M must be added as compensation for rent. The salary of female teachers is somewhat lower. The directors in complete institutions receive.—

Salary initial	After	3	6
	years of service		
6600 M	7200	7800	

The rent indemnity amounts to from 900 to 1800 M. The salary of Provincial School Councillors is 6300 M, rising in three stages to 8000 M, with a rent indemnity of from 900 to 1800 M. The Special Councillors in the Ministry receive 7000 M, rising in three stages to 11,500 M. after twelve years of service. The rent indemnity is 2100 M.

Pensioning of teachers is dealt with by the Prussian Pension Law, Section 1: "Every

## GERMANY

civil servant who draws his salary from the state receives from the same a pension for life when he is incapacitated for the performance of his duties after at least ten years of service in consequence of physical disability or other infirmity or intellectual failing, on account of which he is retired. Where the incapacity is due to illness, wound, or other accident, with which the official has met in the exercise of his duties or through contributory cause with no fault of his own, the right to a pension becomes due even before the completion of ten years of service."

**Section 7.** "Where an official is incapacitated before the completion of ten years of service and is on that account superannuated, except under circumstances referred to in the second half of the first paragraph, in case of destitution a pension for a definite period or for life may be granted with the approval of the King."

When an official is sixty-five years old the claim for a pension is not conditional on incapacity. The amount of the pension is determined as follows: "Where the retirement takes place after the tenth, but before the completion of the eleventh, year of service, the pension amounts to  $\frac{3}{8}$  and rises with each completed year up to the thirtieth year of service by  $\frac{1}{8}$ , and thereafter by  $\frac{1}{10}$  of the income. But there is no increase beyond  $\frac{3}{8}$  of this income." In calculating the pension the whole income last received inclusive of the rent indemnity is used as a basis; local additions are as a rule subject to pensions. In 1906 there were in Prussia alone 10,025 teachers from elementary schools in receipt of pensions, of whom 8381 were male, and 1644 female. The total amount of pensions was 15,007,764 M (13,562,980 M for male, 1,444,784 M for female, teachers); the average pension for males was 1618 M and for female teachers 879 M. Widows and children of deceased officials have also a claim to a pension, in the calculation of which the following provisions are made in Prussia: "The amount received by the widow is 40 per cent of the pension to which the deceased would have been entitled, if he had been superannuated at the time of his death. The sum for widows must not be less than 300 M nor more than 3500 M. The allowance for orphans is. (1) For children, whose mother is living and at the time of the death of the official was entitled to the widow's allowance, a fifth of that allowance for each child. (2) For children whose mother is no longer alive or at the death of the official was not entitled to the widow's allowance, a third of that allowance for each child. The allowance for widows and orphans must not exceed the amount of the pension to which the deceased was entitled or would have been entitled if he had been superannuated at the time of his death."

The conditions treated in the foregoing account are as a whole similar in the rest of the

## GERMANY

federal states, although differing in details in many ways, which cannot be entered upon here. It may be mentioned, however, that occasionally teachers, as other officers, have to contribute to pension funds, in which case the maximum pension is usually higher, as in Bavaria.

Arising out of the fixed and definite position already described and the high professional efficiency due to the thorough preparation, the social standing of teachers in elementary and higher schools is high. For the same reasons these teachers have developed a strong professional feeling, even though it is at present confined to each grade respectively. Just as there is no bridge leading from the ranks of elementary school teachers to higher school teachers, so both regard themselves as separate professions, and the professional organizations of both work entirely independently of each other; but since higher and lower education are separate systems, each with different problems, this separation is not such an evil.

(Based on Lexis' *Public Education in the German Empire*, p. 96.)

**Attendance** — In all German states compulsory school attendance prevails, lasting generally eight years (seven in Wurttemberg), and beginning with the sixth year. In Bavaria there is compulsory attendance at Sunday school from fourteen to seventeen. The extension of school compulsion to the continuation school (*qv*), that is, beyond the fourteenth year to the eighteenth, or up to entrance into the army (which is in itself a powerful educational institution), has not yet been introduced everywhere, but is earnestly striven for. Much remains to be done in this field, particu-

## GERMANY

larly for girls Legal compulsory attendance is everywhere strictly enforced in Germany, and in the last resort is secured with the aid of the police and the courts Only on proof that children are receiving satisfactory instruction privately is exemption from school granted Hence the percentage of illiterates in Germany is almost nil, as may be seen from the tables on page 71

**School and Church.** — The opposition between the Protestant and Catholic denominations (Germany is about one third Catholic and two thirds Protestant) has been one of the greatest influences in German history, and is still one of the most important factors in domestic politics No wonder then that this is reflected in education The public higher schools are almost wholly interdenominational or undenominational (*simultan*); the lower schools are undenominational in only a few states, as in Baden and Hesse, while the denominational elementary schools exist in the largest states, especially Prussia The most important legislative enactments on this question read as follows. "Public elementary schools are to be so organized that Protestant children receive their instruction from Protestant teachers, Catholic children from Catholic teachers" "In public schools with several teachers, either only Protestant or only Catholic teachers are to be appointed" Finally, "when in any school community, which has only elementary schools staffed with Catholic teachers, the number of local Protestant children of school age for five consecutive years is over 60, or in towns and rural communities of more than 5000 inhabitants, over 120, then, provided that the legal representatives of more than 60, or more than 120 children of school age of the class mentioned, make recommendations to the supervising educational authorities, instruction is to be arranged in schools wholly under Protestant teachers," and vice versa Jewish pupils are received into the elementary schools; where a Jewish community is large enough, it may erect a separate school, although their number is in any case very few In 1906 the percentage of children who were in schools of their own denomination was as follows: —

	IN TOWNS	IN THE COUNTRY
	Per cent	Per cent
Protestant . . .	92 20	97 27
Catholic . . . .	87 25	91 47
Jewish . . . . .	30 03	20 37

**Coeducation** — For boys and girls in higher education separate institutions are provided almost everywhere, only a few South German states (Baden, Hesse, Württemberg) admitting girls into the boys' schools; up to the present

## GERMANY

this has not been done in Prussia In the elementary system special girls' schools or girls' classes are provided when the numbers are large enough In 1906, 65 per cent of the elementary school classes in Prussia were mixed, containing 64 per cent of all the children There were 40,376 separate classes and 75,526 mixed classes In the towns, of all the children 1,669,286 were in separate classes and 636,979 in mixed, in the country, 561,537 were in separate and 3,296,596 in mixed classes Thus in the towns separate classes, and in the countries mixed classes predominate

**Cost of Education** — The maintenance of elementary schools as a general rule falls by law on the communities, the state enters only in case of need and gives assistance only to smaller communities The terms of the Prussian law on the subject are: "The erection and maintenance of public elementary schools falls, with the exception of the provisions of this law, on the municipal communities and the independent districts Communities (or districts) either are independent school districts or may be united for the maintenance of one or more schools into one common school district (*Gesamtschulverband*) One community may belong to several union school districts Even when it forms one independent school district, it may belong at the same time to one or more union districts" (Section 1) According to Section 7, "Where the inability of a school district to raise the cost of maintaining an elementary school is proved, subsidies are given by the state Further the state grants to smaller communities a part of the cost for new school buildings" The amount of expenditures for the purposes of elementary education is indicated in the following tables (from *Statistisches Jahrbuch f. d. deutsche Reich*, Vol XXIX (1908), p 153) --

EXPENDITURE FOR PUBLIC ELEMENTARY SCHOOLS

politics also demands the creation of such a system in the growing towns, for this attracts settlers to the town. A few of the higher schools are under royal patronage and possess considerable endowments; a larger number are maintained by the state, but by far the largest belong to communities or towns. There are comparatively few private high schools for boys, although they are slowly increasing in number. Further details of the expenditure for this branch of education are indicated in the table on page 75.

To the figures for 1906 under No 1, 11, 110,091 M ought to be added; this sum comprises contributions by the state for city and country schools which cannot be separated. The total expenditure for public elementary schools for 1906 thus amounts in Prussia to 328,319,147 M.

The single expenditures of the state amounted to 1,408,560 M in 1910 (*Etat*, p 238); the amount spent locally it is impossible to give, but it was certainly far larger, since many new schools are being established, — more by the communities than by the state.

The higher education of girls has up to the

The duty of maintaining the higher schools is not definitely determined by legislature in Prussia. So far as possible the towns maintain their own secondary schools, and frequently make it a matter of great pride to possess a highly developed system of education. Local

present been mainly in the hands of private institutions, the number of which will in consequence of the recent regulations show a rapid decline, and the burden will fall almost entirely on the communities. The current expenses of the state for these schools amounted

Figures from *Etat des Ministre d'gestl etc., Angel f d Etatsjahr 1910, Beilage*

in 1910 to 1,079,583 M (in 1906 only about 330,000 M), single expenses are not yet to hand, the corresponding local expenditures cannot be given but were certainly very considerably higher.

**ELEMENTARY AND INTERMEDIATE EDUCATION** -- The lower schools (*öffentliche Volksschulen*, public, common, or elementary schools) are wholly public, and there are practically no private schools of this type. As a rule no fees are charged. Instruction begins at seven or eight in summer, and eight or nine in winter, and includes four or five, rarely six, periods a day. While the number of pupils may rise to a maximum of 1000 (a figure very rarely attained), the minimum number is small, and in remote places is from ten to twenty. Separate schools for boys and girls are maintained only in larger communities, where the number of pupils is large enough to warrant a separation, and this is the usual practice (See above.)

The teachers by a large majority are men; in 1906 there were in Prussia 138,216 men and 23,708 women teachers. But the percentage of women teachers is gradually increasing. The men teachers give from twenty-six to thirty or thirty-two lessons, the women twenty-two to twenty-six or twenty-seven per week. The division of schools into classes varies according to the size of a community. In the country single and two-class schools with one or two teachers are common, while in the towns systems with eight or nine classes and from

twenty to thirty teachers have been developed. Some details are given in the following table (based on *Statist Jahrb f d preuss Staat*, Vol VII, 1910, p 166) —

	IN THE TOWN		IN THE COUNTRY	
	1896	1906	1896	1906
Average per school of				
Classes	7 11	8 87	1 94	2 22

Children	418	477	109	117
Average per teacher of				
Classes	1 01	0 98	1 25	1 23
Children	59	53	70	65
Average number of children per class	59	54	56	53
Number of classrooms	30,090	42,882	50,221	59,565
Number of children not received on account of overcrowding	578	245	1831	674

**Curriculum** — Such a variety of external conditions is naturally accompanied by a variety of curricula and standards in the individual schools. The single-class schools in which children of all ages are taught together, cannot perform the same type of work as the fully graded school. But all schools of whatever size must conform to certain minimum requirements, of which those of Baden may serve as an example, similar regulations being found in the other states: "The education of the elementary school shall train the children up to be intelligent, religious, and moral persons and upright members of the community. It

# GERMANY

# GERMANY

must cover the following subjects: religion, reading and writing, German, arithmetic, singing, elements of geometry, geography, natural history, and nature study, and history, with physical exercises for boys, and for girls instruction in female handicrafts. The number of periods per week shall be at least sixteen, and from the fourth year on at least twenty, with a maximum of thirty for any class. The following time-table of the Berlin elementary schools may be taken as representative of a large school system —

(The figures in brackets denote deviations in the girls' schools)

The work of these schools may be indicated by the scope of some subjects in the upper grades of a Berlin elementary school —

German the pupils must attain to thorough soundness in oral and written use of the vernacular. Com-

plete thoroughness in orthography and the elements of grammar are expected and reached.

Arithmetic for Class II includes the rule of three, sums with compound numbers, proportion, calculations of everyday life, excluding exchange, discount, and partnership, together with insurance. Class I exchange, discount, and partnership; comprehensive and final drill in calculations of everyday life; arithmetic and algebra (except in girls' schools), the theory of denominate numbers, algebraical addition, subtraction, multiplication, and division, proportion, equations of the first degree with one or more unknowns.

Nature study (physics) in the boys' schools, Class II lessons in inorganic chemistry and mineralogy, magnetism, electricity, galvanism. Class I completion of inorganic chemistry, introduction to organic chemistry, mechanics completed, sound and light. In the girls' schools, Class II Lessons in organic chemistry, especially in its application to foodstuffs, elements of mechanics of solid, liquid, and gaseous bodies. Class I magnetism, electricity, galvanism, sound, light.

Little can be said about the methods of instruction. The teachers are somewhat more restricted than in the high schools, yet not so much as to crush individuality. Closer insight into the methods can only be secured by visiting the classrooms and a study of the textbooks.

The elementary schools do not grant any privileges in the same sense as the higher schools. Some workingmen's guilds demand that their apprentices shall have completed the first class of the elementary school; and such requirements are laid down occasionally in other occupations. The tables given below, compiled from various sources, give additional statistics of elementary education in the most important German states and the Empire as a whole.

**Special Provisions for Abnormal and Super-normal Children** — In an increasing number of towns special schools or classes are being established for the backward (*Schwachbegabte*). In 1905 such arrangements existed in 97 Prussian communities with a school population of

The Mannheim system created by Superintendent Sickinger has aroused considerable attention and much imitation. It not only provides for schools for backward, but also attempts to provide special means for the education of the very bright and gifted pupils. This aim is attained by dividing the school system not only vertically into classes, but horizontally into various types of classes and institutions, and by assigning children to different schools not alone according to the districts in which they live, but according to their ability. By this system the very able children come after two years' attendance at school into classes which prepare them in one and a half years for the gymnasium. Pupils above the average have a richer curriculum, including a foreign language; the normal pupils go through the usual eight years' course, while

# GERMANY

the backward and dull receive courses of from four to seven years.

The following table gives a schematic view of the whole system, the eighth class being the lowest:—

Column A Regular grades containing more than 90% of the pupils

**Middle Schools (Mittelschulen, Bürgerschulen, or Higher Elementary Schools)** — This type of schools is intermediate between the elementary and higher schools, and is distinguished from both chiefly in teaching not more than one foreign language. While they are very frequent in the South German States, such as Baden, and in Saxony, and there form an important part of the school system, they are not so well developed in Prussia, as is indicated in the table at bottom of page 77.

It will be seen from this table that there are middle schools for boys, for girls, and for both together. The expenditure on this type of schools is much less than for higher or elementary schools. The reason for the comparative failure of these schools in Prussia, although such an intermediate stage was really a strong necessity, was that they did not convey any privileges nor prepare for or articulate with the higher schools. New courses of study were, however, issued in 1910 for Middle Schools which mark a great step in advance. While privileges were not granted to these schools, the curriculum has been so arranged that it can prepare for the higher schools. They comprise nine classes or years, and are based on the elementary school in so far as both have a common course in the lower stage. Fees are charged, but a suitable number of free places are maintained. Except in the lower stage there is an average of five periods per day. Good pupils may study a second language from the seventh school year on. In principle every pupil is expected to take only one compulsory subject. By the establishment of minimum and maximum standards, every school has sufficient scope to adapt the curriculum to special needs. These are new principles in the Prussian educational system; moreover the new schedules approach much more nearly to the principle of election and elasticity than any other part of the system. They are accordingly given here in greater detail.

#### Training of Elementary School Teachers

Special institutions have been established for the professional training of teachers for elementary schools, distinct for males and females. The normal schools for men are part of the elementary school system. Between the elementary school and the normal school there is an intermediate school, the preparatory institution (*Präparandenanstalt*). Normal schools and preparatory institutions (of which there are at present only a very few for girls) are usually residential institutions (*Internate*). The preparatory institutions are either attached to or separated from the normal schools proper. They receive pupils from the elementary schools at the age of fourteen and keep them for three years. Attendance at the preparatory institution is not a requirement for entrance to the normal school, and candidates may prepare privately, but must show by examination "that they have attained

the knowledge and ability specified in the course of study for preparatory institutions." The transfer from a higher or middle school to the institutions for the training of teachers is, in Prussia at any rate, not provided for, and pupils who wish to transfer must pass an entrance examination for admission to the class they wish to enter. Pupils come in some cases from a middle or real school, but rarely from a higher school. The course of study of both institutions is given in the following scheme; the normal schools for women deviate somewhat, but only slightly, from this.

<sup>1</sup> Included with subject matter<sup>2</sup> One hour for method<sup>3</sup> Method

The requirements in the normal schools are given in detail in a few subjects and classes —

I *Pedagogy* (A) Theory of Education. First year (3 hours a week) — General instruction in psychology and logic and their application in didactics and methods. Second year (3 hours a week) — Theory of education, history of education from the second semester. Third year (3 hours a week) — Continuation of history of education up to the present time. School organization, hygiene, management and regulations. Advice in regard to further study after graduation.

(B) Training in School Practice. Second year — In connection with model lessons in the practice school given by the practice teachers the students of the normal school are given opportunities all through the year to give lessons which they have prepared, and they receive instructions as to how to proceed. Third year — All the students of this third grade are intrusted with giving lessons and acting as class teachers in the practice school throughout the year under supervision of the regular instructor. Each student must have from four to six hours a week of independent teaching. Two hours a week are to be devoted by the students to preparing lessons with attention to method and subject matter, criticizing lessons given by the students and discussing the school plant, administration, discipline, etc. Besides, these two periods are set aside for model lessons and practice lessons to be given in the different branches by the practice teachers, in which didactics or methods are exemplified. The normal students also are required to attend the lessons given by their colleagues according to previously determined rotation. The practice and special teachers are to familiarize the students with the methods used in each branch of study.

\* \* \*

III *German Language and Literature* — Third year (3 hours a week) — The most notable contemporaries of Goethe and Schiller in connection with their works and their time. Some of the noted modern poets in biographies and in connection with the reading of their works. The German folk song. Dramas *Wallenstein* and one drama of Shakespeare. Prose reading, preferably Herder's and Schiller's prose works. Home compositions once a month. Two compositions in class. Methods of teaching. One hour a week throughout the year.

IV *Foreign Languages* (A) French. First year (2 hours a week) — Review and completion of accidence, the position of words, the use of tenses. Reading. Simple stories in prose, easy poems. Second year (2 hours a week) — The uses of moods, infinitive and participles, declensions and words governing cases. Reading. Easy historic prose author of modern times, poems. Third year (2 hours a week) — Syntax completed and reviewed. Reading. Some historians of modern times, poems.

\* \* \*

VI *Mathematics* (A) Arithmetic and Algebra. First year (3 hours a week) — Powers and roots, logarithms, equations of the first degree with several unknown quantities. Second year (3 hours a week) — Equations of the second degree. Arithmetical and geometrical progressions. Compound interest, computing revenues, annuities, etc. Third year (1 hour a week for arithmetic, algebra, and geometry) — Methods of teaching arithmetic and geometry.

(B) Geometry. First year (2 hours a week) — Proportional-

ity of straight lines and similarity of figures. Stereometry. Second year (2 hours a week) — Continuation of stereometry, construction of algebraic formulae, trigonometric functions and computation of plane figures. Third year (1 hour a week) — See above.

At the end of the course the first teachers' examination is held at the normal school in the presence of a commissioner of the government, the regulations for which are as follows —

The standards of knowledge and ability which are to be required are defined by the course of study of the normal school. The written examinations include (1) an essay on a topic taken from the theory of education or method, history of education, or German literature, (2) and (3) the preparation of an essay in religion and one in history, (4) a translation from the foreign language into German, (5) the preparation of a chorale for those who have taken lessons in organ playing and harmony. For the first essay four hours, for the rest two hours are allowed. The oral examination deals with the positive knowledge in pedagogy, religion, German, history, and the foreign language, and methods of different subjects of the elementary school. Further, those students who showed at the promotion from the second to the third class an unsatisfactory knowledge in nature study and geography are also to be examined in these subjects. A model lesson must be presented.

Candidates prepared outside the normal schools must be examined in all the subjects of the curriculum.

The first examination, however, is not a qualification for appointment as teacher. Such qualification is only obtained by the second examination, which may be passed not less than two nor more than five years after the first. This is not a repetition of the first examination, but aims to discover the ability of the candidate to hold a school appointment. The examination consists of three parts: the written work, which consists in the preparation of an essay on an educational subject, this is followed by the presentation of a lesson on a topic assigned one day in advance, and the oral examination, which begins with pedagogy covering mainly the history of education, principles and method, and school management; the examination in method may include all the subjects of the elementary curriculum, but, as a rule, each candidate is only examined in three subjects. On passing this examination the candidate receives a certificate for permanent appointment as teacher in the elementary school.

Two further examinations may be taken by the teachers. The examination for teachers in middle schools qualifies for appointment in middle schools and girls' high schools. The examination for principals, which may only be taken after that for middle school teachers, qualifies for appointment as director or instructor in normal schools, district school inspector, director of preparatory institutions, middle schools, and elementary schools with six or more classes.

The examination for middle school teachers consists of pedagogy and two of the following subjects: religion, German, French, English, history, geography, mathematics, botany and zoology, physics and chemistry. A thesis, for which eight weeks are allowed, must be prepared by each candidate on a topic from one of his two subjects. Further, there is a written examination of four hours on the two subjects. The oral examination consists of the presentation of a lesson, and an examination in pedagogy and the two selected subjects.

The principal's examination covers only the field of education in its broader sense. A topic is assigned for a thesis, for which eight weeks are allowed, on the theory and method of education and school management. The oral examination covers the whole field of general theory and method, special method of the separate subjects, their history, school ordinances and school management, school apparatus, and aids for instruction, popular and children's literature, etc.

#### Continuation Schools (*Fortbildungsschulen*)

— These schools do not form a part of the school system proper, and differ from that in organization and aims. For further treatment see CONTINUATION SCHOOLS, EVENING SCHOOLS; and especially INDUSTRIAL EDUCATION.

**SECONDARY EDUCATION** — The school year is divided in the same way as the elementary schools. In Bavaria, however, the school year runs from the end of September to the beginning of July. School opens, as a rule, at 7 or 7 30 in summer, at 8 or 8 30 in winter, with five or six periods of forty-five to fifty minutes, occasionally there are some afternoon periods. In the smaller towns there are often four periods in the morning and one or two in the afternoon. The size of the schools is smaller than in America, the maximum, which is rarely reached, being probably 1000 pupils, 400 to 500 being the normal number, while schools with 150 pupils are rarely found.

The higher education of boys and girls is quite distinct, and the two have developed historically along different lines. In a few states (Baden, Hesse, Württemberg) the girls are admitted to the boys' schools, and the tendency to admit girls to boys' schools in small towns, where the numbers are not great enough to call for separate schools for girls, is gradually, but surely, making itself felt.

The boys' high schools are, as a rule, public, there being very few private schools. The entrance requirements are the successful passing of the third or fourth class in the elementary school. Frequently preparatory schools which do this work in three years are attached to the high schools; such schools (*Vorschulen*) in which fees are charged are preferred by the wealthier classes. Every high school is divided into six or nine classes or school years. In the larger institutions each class is duplicated, — the autumn class for those pupils who are promoted in October, and the Easter class for those who are promoted at Easter. In Baden promotions take place only once each year, in July, and the classes are then divided into parallel sections. The following are the names of the classes, their abbreviated form, and the age of entrance into each: —

Lower Stage	Sexta VI 9	Intermediate Stage	Untertertia U III 12
	Quinta V 10		Obertertia O III 13
	Quarta IV 11		Untersekunda U II 14
Upper Stage		Obersekunda	O II 15
		Unterprima	U I 16
		Oberprima	O I 17
		Abiturientenexamen	18

Thus VIO is the Easter group of Sexta; UIM the Michaelmas group of Unterprima. Parallel classes, as, for instance, VIO and VIO<sub>2</sub>, are found only in exceptional cases where the classes are too large. The three stages as a rule form one institution, although there are schools consisting of only the lower and middle stages. Every class is passed in a year, and it is very rarely that a pupil can accomplish the work of a class in half a year, nor is this encouraged. Those who do not reach the standard of a class, that is, are deficient in two major subjects, fail of promotion and repeat the work of that class for a whole year. Promotions are by classes and never by subjects, and are made on a pupil's standing for the whole year and on the opinion of the teacher, examinations for this purpose rarely take place. The marking is at present on the following basis: 1, very good; 2, good; 3, satisfactory; 4, deficient; 5, unsatisfactory. In a few states another mark, 3, good as a whole, is inserted between 2 and 3, and 6 becomes the lowest. Generally a pupil fails of promotion when he is deficient in two major subjects. The maximum size of a class is 50 in the lower, 40 in the intermediate, and 30 in the upper, stage. These numbers are frequently reached in the lower, rarely in the upper, stage. If more pupils enter a class, then a division into two parallel classes is made.

**Curriculum** — There are three types of higher schools with nine-year courses: the gymnasium, the oldest form, with the classical languages as the distinguishing characteristic, the realgymnasium, with Latin, modern languages and natural science, the oberrealschule, without Greek or Latin, but with the modern languages and stronger emphasis on mathematics. German, mathematics, history, and religion are common to all. The following timetables of the three kinds of schools in Prussia show the distribution of the subjects and the number of periods of recitations each week:

## GERMANY

## GERMANY

The brackets denote the possibility of a temporary alteration of number of periods within the same group of subjects. In classes IV and U III a special class is arranged for pupils whose handwriting is bad.

The following changes in the curriculum are admissible. In O II, U I, and O I, English may take the place of French, in which case French may remain an optional subject with two hours a week. In U III, O III, and O II, other subjects may be substituted for Greek; in which case three hours are given to English, and generally in U III and O III two hours to French, and one hour to arithmetic and mathematics, while in U II one hour is given to French and two to mathematics and natural science.

<sup>1</sup> As in the Gymnasium

The extent of the knowledge which is to be transmitted will be indicated through the scope of the curriculum of the highest class in a few of the chief subjects and through the requirements of the final examination (Based on Lexis, Vol. II)

VOL. III — G

*Greek Subjects in Gymnasium* — Reading: Homer's *Iliad*, Sophocles, Euripides, Plato, selections from Thucydides, and Demosthenes, other prose valuable for content, appropriate selections of Greek lyric poetry. Grammar, revision, and recapitulations of the whole subject, as found necessary. Practice in unseen translation. Written translations from and into Greek.

*Latin in the Gymnasium* — Reading, 5 hours. Cicero (e.g. *in Verrem* IV or V, *pro Plancio*, *pro Sexto*, all with omissions, *pro Murena*, selections from Cicero's philosophical and rhetorical writings, also from his letters, Tacitus' *Germania* (at least till Chap. 27), also *Agricola*, or parts of the *Dialogue*, selections from the *Annales* (especially the sections referring to Germany) and from the *Histories*, selections from Horace, memorization of some of the *Odes*. Occasionally, unseen translation. Private reading, especially also of writers read in previous classes, is to be encouraged and fostered, but is not required as obligatory. Grammar, 2 hours. Revision with special attention to the more important and difficult syntactical rules, recapitulating explanations of specially prominent stylistic peculiarities. Translation into Latin, written class and home exercises.

The requirements in Latin in the realgymnasium are somewhat lower.

*French in the Realgymnasium* — The reading, which, as in the gymnasium, occupies a central position, is treated more extensively and intensively than in the latter, so that the pupils may acquire a broader notion of the special qualities of French literature in the last centuries, as well as some knowledge of the national culture and character. Revision and completion of the more important sections of the grammar. An outline of the laws of versification. The essentials of synonymy and of the laws of style. Extension of the vocabulary, including also technical and scientific terms. Written and oral exercises. Exercise in essay writing, from frequent brief production of what has been read, up to a freer treatment of definite concrete subjects. Conversational exercises at every lesson, not merely in connection with the reading and incidents of daily life, but also on the history, literature, and culture of the French nation.

*French in the Oberrealschule* — In these schools the teaching aims at imparting a knowledge of the more important French writings of the last three centuries, insight into the grammatical system of the language, some knowledge of the most important sections of French literary and social history, and practice in speaking and writing.

The scope in English is similar, although essays are not required in this language. The scope of these subjects is correspondingly smaller in the gymnasium.

*Arithmetic in the Realgymnasium and Oberrealschule* — Theory of combinations, and application to the theory of probability. The binomial theorem for any exponents, and the simplest infinite series. Repetition and continuation of the arithmetical course (extension of the notion of numbers by algebraical operations, from the positive integral to the complex number). Cubic equations. Elementary exercises in maxima and minima. Spherical trigonometry with application to mathematical geography and astronomy.

*Geometry* — Elements of descriptive geometry. The most important problems in some sections in elementary-synthetic treatment. Analytical plane geometry. Revision, recapitulation, and exercises in all branches of the subject taught in previous classes.

*Methods of Teaching* — No account can here be given of the methods of instruction in the German schools; an insight into them can only be obtained by a visit to the schools and by a study of the textbooks. General regulations on method are found only to a small extent; like the choice of textbooks, the method of teaching is left to the individual schools. Since school inspection, which might serve to secure uniformity, is very slight in higher education, the variety found in teaching is exceedingly great, and a somewhat firmer restriction placed on the individual teacher would at times not be out of place. A certain amount of uniformity is secured within each institution through the use of the same textbook by different teachers, and in the system itself through the prescription of definite aims whose attainment is assured by means of the final examination, at which an inspector is frequently present.

# GERMANY

# GERMANY

Progymnasiums and realprogymnasiums, which are not very numerous, and the very numerous real schools have each the same curriculum, differing only in that they lack the three, occasionally (especially in Baden) the two, highest classes. Only the Berlin real schools have a somewhat different curriculum for purposes of better articulation with the common schools. French is here begun in Quarta, and more attention is given in the lower stage to arithmetic and mathematics.

**Reform Schools** -- From the accompanying table it can be seen that the transition from the gymnasium to the realgymnasium is quite possible in the first three years, but a change from the oberrealschule and the realschule to the gymnasium or realgymnasium or vice versa is entirely impossible. Hence parents must decide quite early, when their children are nine or ten years of age, on the type of school to which they are to be sent. The feeling that it would be better to postpone a decision which is irrevocable has led to the organization of the reformgymnasium and realgymnasium. A common foundation is laid for the three types of high schools, for which purpose the lower stage of the real school or oberrealschule is employed. At the end of three years there is a bifurcation; one section begins English and continues later with a stronger emphasis on natural sciences (realschule and oberrealschule), the other begins Latin, and after two years is again split up, the one division (gymnasium) beginning Greek, the other (realgymnasium) English. This is the Frankfort system, from which that of Altona deviates somewhat. According to this system either separate institutions may be established for the three types of schools, gymnasium, realgymnasium, realschule,

or oberrealschule, or two or three different types may be united into one institution. The following is the time-table of an institution consisting of a reformgymnasium and realgymnasium (the Leibnitz School at Hanover, where also a special method is employed in teaching Greek, the pupils beginning with the Homeric dialect and poems in U II, and going on to the Attic dialect in O II): --

The following scheme shows a combination of the realgymnasium with the real school according to the Altona system: --

## GERMANY

The aim and, as a rule, the methods of the reform schools are the same as in the corresponding schools of the old type. They are thus by no means new schools, but merely differ in postponing certain subjects in favor of others. Two principles are, however, adopted, new to the traditional German schools which had and still have a fixed course: these are the principles of a common foundation and of bifurcation. Two important changes are thereby effected; first the decision on the choice of an educational course is postponed for several years, and secondly more types of courses can be offered in the same institution and under the same direction. These principles find even wider application in the reform of girls' schools and middle schools. They indicate that the German educational system is gradually abandoning the principle of a fixed curriculum and is accepting the principle of election, — a movement of the highest significance. The Frankfort Plan was originated by Dr Reinhardt, now at Berlin.

The tables in the next column show schematically the relations between, and the articulation of, the three types of higher schools in the old and reform system.

**Leaving Examination (Abiturientenprüfung)** — The requirements correspond to the program of instruction of Prima. The written examination comprises, for all the schools, a German essay and the working of four mathematical questions, each dealing with a different branch, further. (a) In the gymnasium, a translation from German into Latin, and another from Greek into German. (b) In the realgymnasium: a translation from Latin into German; according to the curriculum of each separate institution, a French or an English exercise, viz, either an essay or a translation from German; and a question in physics. (c) In the oberrealschule, a French and an English exercise, an essay in one of these two languages and a translation from German into the other language, and a question in physics or in chemistry.

The oral examination comprises, for all the schools, Christian religious teaching, history, mathematics, and further: (a) in the gymnasium: Latin, Greek, and according to the curriculum of each separate institution, either French or English; (b) for the realgymnasium: Latin, French, and English, and physics or chemistry; (c) for the oberrealschule: French and English, and physics or chemistry.

**Statistical.** — The tables on page 84 will give some information on the number of the different schools, the number of teachers, of pupils, etc.; material of a more exhaustive and detailed character is not available.

**Privileges** — Two kinds of *Berechtigungen*, or of certificates that entitle the holder to certain important privileges, can be acquired in the higher schools: the certificate of admission for the one year volunteer service in the army,

Bavaria (1909)	46	4	9	32	—	51	141
Württemberg (1909)	14	5	10	5	7	88 <sup>1</sup>	129
Saxony	19	12	2	—	—	30	

<sup>1</sup> From *Centralblatt, etc.*, 1909<sup>2</sup> Twenty-one of these schools have one or two upper classes (obersekunda and unterprima)

untersekunda to obersekunda, which takes place after successfully completing the first six years or classes of the whole course (of nine years). The most important privilege acquired by this certificate is the right of serving only one year in the army, whereas otherwise every German has to serve at least two years. The service is voluntary (*Einhjährig Freiwilliger*) in so far as the time of service and the regiment may, within certain limits, be selected by the individual holding the privilege. This is of course of economic importance, but besides it means a social distinction, especially as the officers of the reserve, a much-coveted dignity, are taken from the *Einhährige* only. At the same time this certificate will show that the bearer possesses a certain amount of knowledge and intellectual training, and so a publicly and officially recognized standard of education is established by it which easily can and actually does serve as the entrance requirement for many official and private careers. So this certificate is the indispensable entrance requirement for the intermediate careers (as official or clerk) in the post office, telegraph and tele-

phone service, in the service of the judicial, the provincial, and the local administration, and the state railway service (the higher careers being always filled by university-trained men, the lower ones with men who have had an elementary school training). In this respect the *Einhährigenschein* takes the place of the civil service examination in America. Large business houses and especially banks generally do not take apprentices who have not at least this certificate, sometimes they require even more. The natural result is that a large number of boys remain at school only for the purpose of getting this certificate and leave as soon as they obtain it (see the figures under U II and O II in table above).

b The *Reifeprüfung* is the examination at the end of the full course of nine years of the three different types. It gives the right of admission to the careers of officer in the army and navy, and above all the right of admission to the universities and technical *Hochschulen*, that is, ultimately to the state examinations at the end of the university or technical course. So the *Reifeprüfung* is nearly the only entrance

to all higher walks of life, and certainly to all higher positions of honor and trust in the service of the state; and the social recognition in which it is held is correspondingly high.

The criticism which is sometimes made by foreign observers of the system of privileges shows a failure to realize the function and the importance of this system. It certainly has drawbacks; it is a heavy burden on the boys and on their parents; it keeps many boys in school who ought not to be there any longer, and is therefore a burden on the school. But infinitely greater are its advantages for the life of the nation as well as for the work of the school. By this system definite educational standards are secured throughout the nation, in a reliable way it provides young men with a broad knowledge and thorough intellectual training for the higher as well as for the middle careers in life, it relieves the higher institutions of the burden of elementary work and lays a good foundation for their own work. It puts the examinations where they belong, — at the beginning and not at the end of the course; and though it sifts thoroughly, it avoids the tremendous waste of entrance examinations; it does not place the examinations in the hands of persons who have never seen the boy, but leaves him to his teachers, who have known and worked with him for years; and the boy is not judged by the written work of a few hours, but by the oral and written

work of a year and by his whole personality. The system secures the willing, though not always the hearty, cooperation of the parents. Last, but not least, it exercises an automatic pressure on the boy, which causes him to work, — a pressure which otherwise the teacher would have to exercise by his personal efforts. Thus the school system becomes more efficient. It would be difficult to devise another system which could bring about these same results as economically and as thoroughly. Far from being the "bane of German secondary education," the system of privileges — *Eingängigkeit, Reifeprüfung, Staatsexamen* — is, therefore, the most important reason for the efficiency and thoroughness of the German schools, more important than even the preparation of teachers, which is partly secured only with the help of this system.

The externs, *Extraner*, those who prepared outside of the schools, are not counted in this list. In 1907-1908 at the gymnasiums 368 externs registered, for the examination of whom 253 were admitted and 150 passed; 88 of them were 21 years of age and over, and 85 entered a university. At the realgymnasiums the corresponding figures were, 205, 162, 123, 73, 61, and at the oberrealschulen, 186, 97, 67, —, 23.

**Cadet Schools.** — These schools are to be found in Prussia, Bavaria, and Saxony. They provide for the general training of future officers in the army and are generally boarding schools, with the curriculum of the realgymnasium combined with military practice. In Prussia there are eight preparatory institutions with lower classes (*Sexta* to *Obertertia*) only, and one central institution with the upper classes (*Untersecunda* to *Oberprima*), which is at Berlin-Grosslichterfelde. This horizontal division into lower and upper sections is a special feature of the cadet schools, distinguishing them from the other higher schools. In 1893 in Prussia the number of pupils in the preparatory institutions was 2470, in the central institution 1000. Many officers come also from the regular higher schools, with or without the *Reifezeugnis*. (See MILITARY EDUCATION.)

**Higher Education of Girls.** — For a long time the higher education of girls was not so well cared for as that of the boys, and at times it was almost neglected. But in recent years a strong reform movement has thoroughly reorganized these schools and placed them on a much higher level. Whereas most of them were formerly in private hands and were money-making institutions, a rapidly growing percentage is now supported by the communities; the state, at least the state of Prussia, supports only very few (see p. 74). As to promotion, division of school year, etc., see the general remarks on the higher schools for boys. The classes are generally named 10th class, 9th class, etc., the 1st class being the highest.

# GERMANY

**Organization and Curricula** -- There are separate higher schools for girls in all the states of the empire. Their curriculum, with the exception of mathematics and science, is not widely different from that of the realschulen, and, though frequently one year longer (10 years or 7 without the 3 years of the preparatory school), it is not quite so broad and the teaching not so thorough (partly on account of the absence of privileges, *Berechtigungen*) Those girls who desire to get an education equal to that of the boys or who wish to pass the *Reifeprüfung* are, in some of the smaller German states, either admitted to the boys' schools (as in Baden or Saxony), or to *Mädchen-gymnasien* or *real-gymnasien*, which are in no way different from the corresponding schools for boys in Baden. In Prussia, according to the regulations of 1908, the girls are not admitted to the boys' schools, and the new higher girls' schools are different from the boys' schools. As these regulations of 1908 will be the starting point for a new development and will be more or less adopted by other German states, their most important features must be given here.

In Prussia the higher girls' school proper contains a course of 10 years (or 7 without the 3 years of the preparatory school), which is nearly equal to the 9 (or 6 respectively) years of the realschule. On this course two others are built, both comprised under the name of *Lyceum*: one of two years, to be known as *Frauenschule*, a very undefined course; the other, one of four years, called *höheres Lehrerinnenseminar* (training college for women teachers at the higher girls' schools proper). After the seventh and eighth year of the higher girls' school proper three other courses branch off which lead to the different kinds of *Reifeprüfung*. These courses are known as *Studienanstalt*. The provision of adequate facilities for preparation, corresponding to the education of the gymnasium, will lead to the admission of women to the universities as fully recognized students, and has already led to new regulations, to take effect in 1913, of demanding university study from teachers in the higher girls' schools. (See Prettyman, C. W., *Higher Girls' Schools in Prussia Teachers College Rec.*, May, 1911.) The influence of the Reform Schools and the principles therein expressed, a common foundation and bifurcation, will be easily recognized.

The following tables show the system, the articulation of its parts, and the different curricula:—

NOTE The perpendicular strokes (|) denote transition from one class to another or to another department, the horizontal brackets (---) indicate the possibility of giving instruction in common in certain subjects to pupils in different classes.

<sup>2</sup> Method and introduction to professional literature

<sup>3</sup> Method and introduction to experimentation

The curriculum of the *Studienanstalten* is almost the same as those of the corresponding boys' schools, but as the whole course lasts

# GERMANY

thirteen years (instead of twelve as in the boys' schools), the number of recitations per week is a little less. Those who have completed the course of any of the *Studienanstalten* may enter the highest class, practical year, of the Seminar.

The higher girls' school proper and the *Frauenschule* have no privileges, the *Reifeprüfung* at the end of the *Studienanstalten* grants the same privileges as that of the gymnasium, etc. As at present there are only about 35 *Studienanstalten* in Prussia, and as the girls are not admitted to boys' schools, many girls who desire a higher education can get it only with difficulty, especially in the smaller towns. Financial or other statistics in suitable form are not available, as the whole system of girls' schools is in a rapid process of reorganization and readjustment, it would in any case be useless to quote statistics.

## Training of Teachers for the Higher Schools

— The teachers in boys' schools are men, most of them with university training, in the girls' schools there are partly men and partly women teachers, most of the women being trained in the training colleges mentioned above, though an increasing number of women are receiving the same university training as the *Oberlehrer*. Admission to the profession of teaching in all the states is dependent on the passing of a special examination for teachers in higher schools, e.g. in Prussia (*Prüfung für das Lehramt an höheren Schulen*), held by special examining boards and independent of the universities, and also a course of practical preparation of from one to two years. A university degree is not a qualification for a teaching appointment, although professors of the universities are frequently members of the examining boards.

*The Examination in Prussia* — To be admitted to the examination a candidate must hold a certificate of graduation from a German higher school and must have studied for at least six semesters at a German university. As a rule the period of study lasts from four to five years or more. The examination consists of two parts, general and special, and both are written and oral. The subjects of the general examination are the same for all candidates and include: philosophy (the most important facts of its history, the chief principles in logic and psychology, the knowledge of an important philosophical work), pedagogy (the philosophical principles underlying the most important facts of its history since the sixteenth century), German literature (general development from the eighteenth century, the knowledge of a few important works), religion (content and coherence of the Bible, general outline of the history of the Christian church, the principal doctrines of the denomination of the candidate). In the special examination there must be one of the following combinations: Latin and Greek, French and English or Latin, history and geography, religion and Hebrew, Greek,

or German, pure mathematics and physics; chemistry, including mineralogy, and physics, or, in place of physics, botany and zoology. Other possible subjects are applied mathematics, and, occasionally, Danish and Polish. In the first three combinations German may take the place of any one subject. The requirements in any of the subjects mentioned, except Hebrew, are divided into two stages: the second grade covers the lower and middle classes including *untersecunda* (minor subjects); the other, the first, includes also the upper classes (major). A candidate is successful when he satisfies in the general examination, and passes in at least one major (first grade, *Lehrbefähigung für die erste Stufe*) and two minor subjects. A large number of subjects may, however, be selected by the candidate, as, for instance, two major and one or two minors. The examination is conducted as follows. The candidate must in the written examination prepare privately two essays, one for the general and the other for the special examination. The wishes of the candidates are considered so far as possible. Sixteen weeks are allowed for the preparation of these essays, although an extension of sixteen more weeks may easily be obtained. A doctor's dissertation or some other printed work may be accepted in place of one of the two essays. A further written test of at most three hours' duration may be imposed, and is in any case required in modern languages. This is followed by the oral examination which lasts about an hour for each major subject and half an hour for each minor, although these periods are nowhere prescribed definitely. Reexamination, extension and supplementary examinations are permitted, but not more than twice for each one of these.

The following requirements of the Prussian Examination Ordinance in a few important subjects are added to indicate the scope of knowledge expected —

*Latin and Greek* — (a) Second grade. A sound knowledge of Greek and Latin grammar, ability in the written use of both languages so far as to translate suitable passages with grammatical correctness and, in Latin at any rate, without any striking defects of style, ability, on the basis of systematic and thorough reading of the classics, to understand, and, omitting passages of special difficulty, to translate readily, selections from works suitable for *sekunda* in the gymnasium. Candidates must possess such a knowledge of Greek and Roman history, including the history of literature and antiquities, mythology and prosody, as to give the necessary explanation on these points of authors to be read in the middle stage, and to be able to employ intelligently good reference works in the preparation of lessons.

For the first grade the additional requirements are a thorough scientific knowledge of grammar, readiness in the written use of Latin, grammatical correctness in the written use of Greek, and ability to speak Latin, wide reading knowledge of the Greek and Roman classics, especially such as serve to enrich the lessons in the gymnasium, and scientific training in the method of explanations, acquaintance with prosody, so far as it bears on the poets to be read in the gymnasium, and practice in appropriate rendering of verse, a knowledge of the general literary development, particularly the best periods, sufficient acquaintance to guarantee further systematic study of the principal periods in Greek and Roman history, political institutions, private life, religion and mythology, and philosophy of the Greeks and Romans, a knowledge of archaeology so far as necessary for effective illustration of lessons by intelligent employment of an appropriate selection of objects. The candidates must also

give evidence of a knowledge in outline of the development of philology.

*English* — After giving evidence of a knowledge of elementary Latin grammar and ability to understand and to translate at least easy passages in the school authors, such as Cæsar, the requirements in this subject are (a) for the second grade. A knowledge of the elements of phonetics, correctness and thorough familiarity in pronunciation, a knowledge of accent and syntax, and elementary synonymy, the possession of a broad vocabulary and knowledge of idiom, and some ability in oral use of the language, a knowledge in outline of the development from the time of Shakespeare of English literature, in which the works of the most important writers in prose and verse must be read, readiness in correct translation of the usual authors into German and in free, written composition in the foreign language without serious errors of expression and style. (The requirements in French are very similar.)

(b) For the first grade. In the written and oral use of the language there is expected not only complete grammatical correctness based on a scientific study of grammar, but a thorough acquaintance with the vocabulary and the peculiarities of idiom, together with a satisfactory ability to employ them for purposes of instruction, a knowledge in outline of the development of the language from the Old English period, and the general development of literature together with a detailed study of the more important works in the past and present, familiarity with the rules of English prosody in the early and modern periods, acquaintance with the history of England so far as necessary for the material explanation of the common school authors. Where the knowledge of the historical development of the language is not so detailed a very able and thorough knowledge of modern literature and an excellent command of the modern language may be accepted as an equivalent.

*Pure Mathematics* — (a) For the second grade. A sound knowledge of elementary mathematics and acquaintance with analytical plane geometry, especially with the chief qualities of conic sections and the principles of differential and integral calculus. (b) For the first grade. Such a familiarity with the principles of higher geometry, arithmetic, algebra, higher analysis, and analytical mechanics, that the candidate can solve a not too difficult problem out of this field.

*Physics* — (a) For the second grade. A knowledge of the most important principles and laws out of the whole held of this science, and ability to prove these laws mathematically, so far as possible without the application of higher mathematics, an acquaintance with the instruments necessary for school instruction and practice in using them. (b) For the first grade. A more detailed knowledge of experimental physics, and its applications, acquaintance with the fundamental investigations in one of the more important branches of theoretical physics, and a general view of the whole field.

The requirements described are those of Prussia, and they are similar in other states with noteworthy differences in Bavaria and Württemberg. In both these countries every candidate has to pass two examinations at an interval of two or more years, and the preparatory work to be done at the university is more strictly prescribed, while the oral and written examinations are conducted differently (see Morsch). Only the following states have agreed to mutually recognize their respective examination certificates, Prussia, Saxony, and the smaller Saxon states, Mecklenburg-Schwerin, Brunswick, Alsace-Lorraine, and some of the smallest states which have no examining boards of their own.

*Practical Preparation* — The certificate of success in the written examination does not qualify for the appointment of teacher. Such qualification is obtained only by practical training of one, but generally two years. This consists, according to the Prussian regulations, of a Seminar year and a probationary year.

*A The Seminarjahr* — During this year candidates must become acquainted with the theory and principles of education in their application to the higher schools and with the method of individual subjects of instruction, and must be introduced to practical work as teacher and educator. For this purpose they

## EDUCATION IN GERMAN STATES

are assigned in groups of eight or ten to a school, where at least two hours of discussion take place each week chiefly on the following subjects: principles of education and instruction and method, especially of the subjects of the candidates; historical survey and discussion of contemporary questions, the character, organization, and curriculum of the higher schools; the school ordinance, principles of school discipline, hygiene, etc., administrative authorities and their organization; service regulations of teachers; and, finally, directions for observation of lessons. The candidates must bring short reports or deliver oral lectures on all these subjects. In their particular work, they must acquire by class-room visitation a survey of the tasks of the whole school. The trial lessons of the candidates begin as soon as possible, and the problems, which at first are kept within narrow limits, are generally made broader and more extensive. Each candidate must give a trial lesson about once in four weeks, at which all the candidates, the director, and the subject teacher must be present. This is followed by a general discussion and criticism. About two months before the close of the year every candidate must hand in a somewhat larger dissertation which demands theoretical considerations and practical applications and should be based on the candidate's own experience and observation.

**B The Probationary Year (Probejahr)** — This period serves mainly to afford the candidates practice in the application of the educational knowledge and ability acquired in the seminar-year, and is usually spent in another institution. The candidates are intrusted with larger, more continuous problems for eight or ten hours a week, always under the more or less strict supervision of the director and those teachers in whose classes the candidates are teaching. As evidence of the amount of pedagogical insight attained the candidates must hand in a report of their own work as teachers. It is only then that the certificate qualifying for appointment in a higher school can be granted, and with it ends the training of the young teacher.

**Reform in the Higher Schools** — Only the most important of the reform movements and ideas can be mentioned here without any further discussion. The following are movements which have been realized here and there without any general acceptance as yet: the introduction of boarding schools; the admission of girls to boys' higher schools; the introduction of biology, philosophy, and civics; closer attention to the modern scientific theology in religious instructions, and, above all, greater freedom and consideration of the interests of the pupils in the upper stage. Possibly there should also be added here the frequent demand for more professorships of education. The following opinions, which have remained nothing more and of which one or the other may be

realized in the future, may be referred to lessening of the home work and the number of subjects in the curriculum, establishment of vocational classes, special promotion of pupils of more than average ability, separation of the upper stage and the establishment of an intermediate institution between the school and the university, somewhat like the American college; and a number of other radical ideas which cannot be mentioned here. It is a pretty generally accepted opinion that the German higher school system, as at present organized, cannot last any length of time, but how it is to be reformed is a problem. But those concerned in it are convinced that reform will not be brought about by a revolution, but by gradual, even slow, but unceasing development.

P Z

**UNIVERSITIES — Historical** — (1) Although the German universities are considerably younger than the famous *Studia generalia* of Italy, France, England, and Spain, Germany from the beginning played an important part in medieval culture. At Bologna and Paris German students and teachers made very creditable contribution to the universities, and in Germany itself schools of the orders like the Dominicans and Franciscans at Cologne, where men like Albertus Magnus, Thomas Aquinas, and Duns Scotus taught, were close rivals of the foreign universities. But the universities proper only sprang up in Germany in the middle or, if the whole of present Germany is considered, towards the end of the century.

In order of time two groups may be distinguished. (1) 1349–1415. Prague 1349, Vienna 1365, Heidelberg 1385, Cologne 1388, Erfurt 1392, Leipzig 1409, Rostock 1419. By the establishment of a *studium generale* at these places the educational organization of Southern and Western Europe was transplanted into German territory. (2) 1456–1506. Greifswald 1456, Freiburg 1457, Basle 1459, Ingolstadt 1472, Trier 1473, Mainz 1477, Tübingen 1504, Wittenberg 1504, Frankfurt-on-the-Oder 1506 (*qv*). The establishment of these institutions was a natural consequence of the new intellectual movement of the time, the Renaissance, but a greater cause was the concentration of political power in the hands of territorial princes. To strengthen their influence these rulers confined the clerical and intellectual life within their own borders and found need for their own territorial university. All these universities, including the older, did not originate independently as did Paris out of the association of famous teachers and their students, but definite political aims contributed to the rise of each. Hence the life of the students was not regulated by a democratic constitution similar to that at Bologna, but the statutes were imposed from above, generally modeled on those which had in the meantime been developed in Paris. However much the secular power may have done for the

establishment, granting of privileges and organization of a university, in its whole work and character it was regarded entirely as an ecclesiastical and clerical institution. Not only did the faculties receive the right to teach and grant academic honors through the papal bull, but in its general attitude and sympathy the university belonged to the clerical estate. The success and influence of these numerous universities on the culture of Germany, in spite of the ridicule of the humanists and the charges of the Reformers, were both very great. Neither movement would have been possible without the preparatory work of scholasticism fostered by the universities. According to Eulenberg's investigations about the year 1500 there were from three to four thousand natives and some two thousand foreign students in Germany. How great must even then have been the number in the German population of university-trained men!

(II) At the beginning of the sixteenth century scholasticism was driven out in Germany as elsewhere by the humanistic movement. But just as the triumph of humanism seemed about to be completed, a new and stronger movement, the Reformation, began and destroyed almost entirely the hopes of victory. Since all intellectual activity had until then been clerical, the general attack on clericalism was bound to lead to a vast upheaval of the whole educational system. But the confusion was soon overcome, for in the first place the German Reformers required for the success of their work a far better educated clergy than the old church, to be able to preach the "pure word of God," the pastor must have studied. Secondly, the secular powers also needed a thoroughly well-trained legal profession for the new duties which were thrust on them by the increase of territorial rights, confiscation of church property, and the acceptance of Roman law. Under pressure of these needs the crisis was overcome and the universities in Germany became territorial institutions for the purpose of meeting the demand for theologians and lawyers. The deeper the cleavage between the Catholic and Evangelical (including Lutheran and Reformed) churches became, the more rigorously was the territorial principle applied to the universities. New universities were added in great numbers; Protestant were Marburg (1527), Königsberg (1544), Jena (1558), and Helmstedt (1576), Catholic included the two Jesuit universities of Dillingen (1549) and Würzburg (1582) (*qq v*). The older universities were also reorganized to meet the new requirements. The smaller principalities and free towns added to their gymnasiums a course of academic lectures, for such an "academic gymnasium" enabled the poorer states to train up theologians and jurists above suspicion from among their own sons. While in the medieval period the majority of the students had been content with

a training in the fourth and lowest faculty, arts, they now sought a professional training in law and theology, with the result that the numbers in these superior faculties increased. Medicine and science still remained almost insignificant. Instruction in all the faculties had taken over from humanism the watchword "Back to the sources," a worship above all of the three sacred tongues, and for daily use a number of new textbooks, but in practice there continued, even in Protestant Germany, the characteristic forms of scholastic method throughout the whole of this period. The intellectual standard of the universities rose somewhat during this period as compared with the earlier, but hardly at the same rate as the general intellectual progress. The epoch-making science of the day, the mathematical, was excluded from the universities, and the contributions of Copernicus, Galileo, Kepler, Descartes, Newton, Leibnitz, were made outside of these institutions. Exhausted as they were by the devastation of the Thirty Years' War (1618-1648), the universities were not in a position to continue their progress.

(III) Research in modern science, which in France, England, and Italy was promoted by academies or societies, in Germany gradually began to center round the universities. Leibnitz, it is true, had already in 1700 called into existence at the Royal Court in Berlin an academy modeled on the Académie des Sciences in Paris, and the Royal Society in London, followed in 1757 by the establishment of the Gesellschaft der Wissenschaften at Göttingen in the Kingdom of Hanover. But the intellectual modernization of culture in Germany did not proceed from the associations of investigators, but from the professional chairs. Hence the academies in Germany are up to the present but of secondary importance and consist of associations of university professors meeting for definite and specialized research.

The new era was opened by the establishment of the Prussian University of Halle in 1694 as a conscious protest against the traditional studies. The modern movement was there inaugurated by three professors: (1) The pietist, August Hermann Francke (*qv*), who broke through the prevailing theological orthodoxy, (2) the leader in the enlightenment, Christian Thomasius (*qv*), who swept out of existence the prevailing formalistic prejudices and superstitions in political and ecclesiastical law; (3) the rationalist, Christian Wolff, who tore down the scholastic barriers between philosophy, mathematics, and natural science. The modern principle of academic freedom now begins its triumphant course. Instruction is now marked by the lecture method with which is introduced the use of the vernacular. While French culture above all had exercised a profound influence on Prussia, the University of Göttingen, founded in 1737, was influenced by the connection between the kingdom of

Hanover and England. Göttingen took Halle as a model, and in addition to jurisprudence promoted the study of the natural sciences and introduced the modern study of the classics; not the mere imitation of ancient models in poetry and eloquence, but a complete entering into the spirit of classical antiquity from the literary, historical, and æsthetic standpoints. Halle and Göttingen were followed in 1743 by the foundation of Erlangen. At the end of the eighteenth century the new ideas had become firmly established in the German universities.

(IV) At the time that Napoleon reorganized the French universities on the principle of the strictest possible control of academic learning and teaching (1808), Prussia, conquered and deprived of all power, established the University of Berlin (1810) on the widely different basis of the greatest academic freedom. Intellectual power was to replace what Prussia had lost materially, and the training in pure idealism was to be left entirely to the influence of truth and freedom. While the universities had hitherto been conducted like schools, with the professors as masters and the students as apprentices, the University of Berlin was to be a free intellectual working community with the professors as masters and the students as their assistants, both occupied in common with the solution of the same tasks. This principle soon found its way into all German universities and laid the foundations on which was built up Germany's unique position in international culture. Soon after Berlin, Breslau (1811), Bonn (1818), and Munich (1826) were founded. A number of the older and smaller universities had disappeared in the Napoleonic period. No new foundations were made in the nineteenth century in spite of the great increase in population. It is only within recent years that it has been proposed to add to the existing number of universities. In 1902 Münster was transformed from an Academy for Catholic Theologians into a university. Recently it has been agitated to establish universities on a basis of voluntary endowments and municipal grants, and in 1914 such an institution will be opened at Frankfurt-a-M (*qv*), while another is proposed in Hamburg. Hitherto it has been unnecessary to increase the number of universities, since in their inherent organization the existing institutions have been much extended and have become specialized. The two great tendencies of the nineteenth century, the great specialization in the intellectual work especially and the remarkable development of natural science, led to a demand not only for a great increase of instructors and a narrow specialization of studies, but also for a development and a constant increase of all the numerous intellectual institutions connected with a university. Since the chief aim of university instruction is to make men of the students, not only imbued with the spirit of their subject,

but ready to carry it forward step by step, the German university requires in the first place learned seminars and scientific laboratories. In the philosophic-historical subjects, in theology, jurisprudence, philology, etc., the seminars, in which the master and his assistants investigate the problems in their field, necessarily required in the course of the nineteenth century more complete equipment, while in medicine and the natural sciences more suitable and more specialized clinics, laboratories, and experimental institutes had constantly to be provided. Since the expenditure on the institutes is much greater in the larger than the smaller universities, a certain amount of inequality arose among them, only compensated for by the fact that the student is enabled to be more directly and personally associated with his director in the smaller than in the larger institutes. As far as the quality of professors is concerned there is no distinction at the different universities. It may be that a few places have one or two men of repute or even geniuses among their professors, but Germany is thus distinguished from other countries by the fact that in essence all the universities are alike, and the same may be studied in Freiburg or in Königsberg as in Berlin.

**Present Position — Relation to the State —** Universities may be established only by the state or with the approval of the state. All the existing universities are state institutions, and as such juristic persons in public law. Their rights, however, as a result of the federal character of the German Empire vary somewhat. As a rule they are not based on legislation but on special privileges, statutes, and ministerial decrees. The income of the universities is very slight, and only a few have sufficient interest-bearing property to be able to cover an appreciable portion of their maintenance at their own expense. Generally they are maintained by the state. The state university budget must, like the state budget, generally receive the approval of the regular representative bodies, and at the discussions the public can, through its representatives, make its wishes with reference to the universities felt. The states do not allow any one to hold an appointment in the church, in the judiciary or higher administrative service, and permit no one to practice law or medicine who has not studied in a German university and then passed the prescribed state examinations. These state privileges are more important for the universities at present than the right to grant academic degrees. The authority in Prussia to which the universities are subjected is the Ministry of Public Worship and Education, which appoints a representative, Curator, or Chancellor for each university, with charge of the external affairs.

The internal administration is in the hands of the universities themselves through the Rector and Senate. The Senate consists either

of several full professors (*ordentliche Professoren*) or generally of annually changing committees of the same body. The Rector or, in some states where the hereditary ruler holds this position, the Prorector is elected annually from the ranks of the full professors, and his election must receive the approval of the state. He presides over the senate. The professors are civil servants with certain privileges. Full professors are appointed by the state or the ruling prince on the responsibility of the Ministry, when as a rule the suggestions of the Faculty or the university are respected. The state also appoints associate professors (*ausserordentliche Professoren*) and confers the professorial title. Again the universities are represented in the legislature of the state by each sending one professor *ex officio* to the Diet (upper House) of their respective state.

*Relation to the Church* — This in Germany is in some ways simpler, in some more complicated, than elsewhere. It is simpler in that both university and church are under the same authority, both being state institutions. Other denominations than the evangelical or Roman Catholic are of little significance, since their membership is too small. But it is this very close connection between Church and State that leads to great complication. The Catholic Church is opposed to the fundamental principle of the German universities, absolute academic freedom, while a strong section in the evangelical church is at any rate not friendly to it. This in view of the strength of the Catholic party in politics leads to parliamentary conflicts on the question of intellectual prescription and on the so-called destructive activity of the "atheistic" professors. So far as individual theological faculties are concerned, the opponents of academic freedom in the evangelical church seek the cooperation of the local synods in filling theological chairs. Hitherto the state

authorities have opposed these tendencies. Yet in practice some concession was made to them in filling chairs not in accordance with the qualifications of candidates and the suggestions of the university, but on the basis of distributive justice (*justitia distributiva*) between the right and left wings of the clerical political parties, with the result that science invariably suffered. In the Catholic theological faculties the present modernist movement has caused the state authorities considerable difficulties; what, for instance, should be the attitude of the state when a professor of theology, appointed by the state with a guarantee of academic freedom, refuses to accept the prescription of his church in his teaching? or again, when a university receives into its midst professors who have taken this oath and thus have abjured their freedom? A solution of this situation has not yet been discovered. The following Prussian universities have evangelical theological faculties: Berlin, Bonn, Breslau, Greifswald, Halle, Konigsberg (all for the old Prussian state church), Gottingen (for the state church in the Prussian province of Hanover), Marburg (for the state church in the province of Hesse-Nassau), and Kiel (for the state church in the province of Schleswig-Holstein). Besides there are evangelical theological faculties at Erlangen (Bavaria), Leipzig (Saxony), Tubingen (Wurttemberg), Heidelberg (Baden), Giessen (Hesse), Rostock (Mecklenburg), Jena (Thuringian States), Strassburg (Alsace-Lorraine). Catholic theological faculties exist in Prussia at Bonn, Breslau, and Munster, in Bavaria at Munich and Wurzburg; in Wurttemberg at Tubingen, in Baden at Freiburg, in Alsace-Lorraine at Strassburg. These university faculties, however, do not suffice for the demand for the Catholic clergy in Germany, and there are in addition six state Lyceums (five in Bavaria and one in Prussia) in which the professors are appointed by the state, one episcopal Lyceum in Bavaria, and seven episcopal theological institutions (six in Prussia and one in Lorraine) in which the professors are appointed by the bishops. Although several universities retain their denominational title from their origin, *e.g.* the Evangelical University of Halle, they are in fact wholly undenominational. Jews are admitted to the teaching bodies everywhere in a percentage far above their number in the population. However, the complaints of the Jews that they are overlooked for promotions are not rare and frequently not without reason.

*Organization* — The universities are still organized according to tradition into four faculties. No university has less than four faculties, only the recently founded University of Munster is still without a medical faculty. In single instances only is there a faculty of political science as distinct from that of law, and a mathematical-natural-science as distinct

from the philosophical. In a broader sense the faculties include the whole *corpus academicum*, the teaching body as well as the students. In the narrower sense the faculty consists only of a section of the teaching body, the full professors in the respective faculty. These elect annually from their midst a dean as director of their business. They are responsible for the regular conduct of instruction in their field, suggest names to the Minister in filling vacant chairs, for the distribution of definite courses to other instructors, for the promotion of private docents (*q v*) and associate professors, etc. They further arrange the schedule of lectures and arrange the hours among themselves, determine on the admission of private docents, and are the authority responsible for the conferment of academic degrees.

The full professors (*ordentliche Professoren, ordinari*) are almost the sole and exclusive bearers of all the rights of the academic teaching bodies. Each of them has a teaching commission for a definite subject and is as a rule bound to conduct a more comprehensive private course in his field and one free public lecture of one or two hours. He receives, first, a definite salary, as a rule 4000–6000 M (\$800–1200) a year, and a slight indemnity for rent, secondly, the fees paid by the students for the private courses, usually 5 M an hour each semester (although in Prussia when fees exceed 3000 M, half of the excess must be paid into the treasury), thirdly, increments granted at the discretion of the Minister who wields a great power, fourthly, fees for graduation and examinations. Professors of medicine conduct to some extent their private practice, and as compared with the great income from this source their salary is insignificant. Similarly, professors in other applied sciences frequently have considerable additions to their salaries.

In addition to the full professors there are a number of others: (1) Honorary full professors who have the rank of full professors but nothing more; (2) titular professors or private docents who have only the title of professor but nothing more (3) Associate professors (*ausserordentliche Professoren, extraor-*

*dinari*) are divided into two classes according as their salaries are or are not permanently included in the university budget. The latter receive no salary, though they often receive a remuneration, as when they are assigned to give a definite course. Such assignments are also made occasionally to private docents. The deciding question in this confusion of titles and positions is whether an instructor is provided for in the budget, for although he does not as a consequence receive a seat or a voice in the faculty, yet his teaching is recognized as within the university. Of greater importance, however, in the applied sciences is it that he conduct his own institute, and is thus independent of other professors. In the case of private docents it is to some extent a limitation of this academic freedom that they are dependent on the good will of full professors for the use of equipment in the applied sciences. The number of associate or extraordinary professors is very large, since with the constant specialization in all sciences and the comparatively slow increase of full professorships the work of the university could certainly not be carried on. The salary of an associate professor who is paid by the state rises in Prussia from 2000 M to 4000 M in twenty years. Many professors never rise above the grade of associate professor because there is no full professorship at all in their subject.

The ranks of the professors are as a rule filled from among the private docents (See Docent for method of appointment, etc.). It is the exception for a man to be called from practical work as pastor, judge, doctor to fill a chair, but in some faculties is not quite so rare an occurrence.

A number of young scientists are also employed to assist the professors. Frequently in the applied sciences a private docent is also appointed as assistant, in such cases his dependence on the full professor is thus correspondingly greater.

*Student Body* — The requirement for matriculation as student in a German university is the possession of the maturity certificate (*Reifezeugnis*) of a secondary school (*Gym-*

<sup>1</sup> The addition refers in every case to Honorary Professors

*nasium, Realgymnasium, or Oberrealschule*) The certificate of certain professional schools is also accepted in some universities for further study in the special subjects; thus, the graduates of industrial schools are under certain circumstances permitted to take up the study of mathematics and natural science, or graduates of normal schools for elementary teachers may be admitted for the study of pedagogy, *e g* at Leipzig, Jena, Giessen, and Tübingen. Women who have fulfilled the same requirements as men are also matriculated, although there are individual professors who do not admit women to their classes. Foreigners are admitted everywhere, if they can show satisfactory preparation. Besides the students there are further registered auditors (*Horer*). At Giessen permission to visit is granted by the Curator for four semesters, which may be extended to six. Such registration is only allowed in the faculty of philosophy. Almost universally the students enjoy complete freedom of study (*Lernfreiheit*), but since the regulations for the professional examinations, which are taken at the close of the academic career, prescribe a definite course, the students in most subjects, and especially law, are confined to a more or less regulated curriculum.

The enrollment in the summer semester of 1911 was 57,330 distributed as follows: Evangelical theology, 1834, Catholic theology, 2825, law, 11,023, medicine, 11,927, philosophy, 29,721. These figures include 2522 women. In addition there were 4060 auditors. The students were distributed as follows in the individual universities: Berlin, 6039, Munich, 6942, Leipzig, 4888, Bonn, 4174, Freiburg, 3080, Halle, 2681, Breslau, 2586, Göttingen, 2492, Heidelberg, 2452, Marburg, 2302, Tübingen, 2118, Strassburg, 2071, Münster, 2009, Kiel, 2001, Jena, 1902, Königsberg, 1517, Würzburg, 1449, Giessen, 1315, Greifswald, 1180, Erlangen, 1104, Rostock, 920. (See also COLLEGE AND UNIVERSITY STUDENT ATTENDANCE.)

#### NUMBER OF STUDENTS COMPARED WITH THE EXPENDITURE OF THE PRUSSIAN UNIVERSITIES

(*Preuss. Statistik*, Vol 223, p 7)

	NO. OF STUDENTS	TOTAL EXPENDITURE <sup>1</sup>	EXPENDITURE PER HEAD PER STUDENT
		M	M
1868-1869	7338	3,886,633	530
1877-1878	8510	7,007,647	823
1887-1888	13,720	9,180,603	669
1896-1897	13,861	11,417,345	824
1905-1906	20,255	15,426,684	762
1908-1909	22,717	17,428,242	766

<sup>1</sup> Covered in the main by the state fund, partly from the property of the university. In Prussia, two-thirds in 1868, and in 1908-1909 three quarters of the expenditures were borne by the state. The expenditures of the non-Prussian universities are as high as those of Prussia.

The students are partly organized in free societies (*Corporationen*), partly unorganized. The method by which the student organizations among themselves or for the whole student body form committees for the supervision of student interests varies from place to place. The German student does not live in college or similar hostels, but in private houses. Hostels exist only for Catholic theological students, and at Tübingen also for a number of evangelical students. Elsewhere there are small endowments for students of small means. Fees and dues are low. University life only becomes expensive when the student, only just out of school and entering on independence but with high spirits and small financial experience, adopts an expensive mode of life. Extravagance, however, is foreign to the German student or is confined to a small circle, as at Bonn and Heidelberg. But generally the men lead a steady life and work with a will, despite their great freedom.

The period of attendance at the university varies with the different faculties. The following are the number of semesters spent on the average in the last decade: Evangelical theology, 7.37, Catholic theology, 7.04, law, 6.86, medicine, 11.00; philology and history, 9.10, mathematics and natural science, 8.88. The academic degree which prevails in the legal, medical, and philosophical faculties is still only the Doctorate (Dr. Jur., Dr. Med.; Dr. Phil.). In the theological faculty there are two degrees, the licentiate and the doctorate (Lic. Theol. and D. Theol.). All these degrees are of practical significance only to those who look to an academic career, otherwise they are merely ornamental. They may be obtained in course by the presentation of an independent work of scientific value and an oral examination before the faculty, or they are conferred *honoris causa*. The doctorate in theology is now only conferred as an honorary degree. The technical term for graduation is *Promotion*. Modeled on the university degrees is the title of Doctor of Engineering (Dr. Ing.), conferred by the technical high schools.

In addition to the universities there is an appreciable number of technical high schools, commercial academies and high schools, academies of forestry and mining, veterinary and agricultural high school. To these must be added the military school, such as the war academy, artillery and engineering schools. More intimately connected with the universities, in aiming not at professional education, but at intellectual advancement, are the public lecture courses at the institutions at Frankfurt-a.-M. (*qv*), Cologne, and Hamburg, the Royal Academy at Posen, and the Berlin Academy for Medical Training for the Army, equivalent to a medical faculty. In university extension work significant beginnings have been made in Berlin (Humboldt Academy, Free High School, Society for Popular Courses by Berlin

University Instructors), at Dresden (*Gehestiftung*), and at Frankfurt-a-M

**LEARNED SOCIETIES** — The societies and associations for the advancement of learning are divided into two classes: the academic or royal societies subsidized by the state, and the general associations founded privately to promote some branch of study. Such associations vary in the character of their work and contributions from the small local society of amateurs and public school teachers to the academic society consisting of carefully trained specialists. It is calculated roughly that there are about one thousand associations founded for purposes of promoting studies throughout Germany. None of these attempt any instruction beyond the reading, discussion, and circulation of reports among members. Some offer prizes for works of original research on a prescribed theme, others for works on any topic, others again subsidize the carrying out of some piece of research. It is impossible here to do more than to mention the state-endowed academies.

The earliest German academy is the *Kaiserlich Leopoldinisch-Karolinische deutsche Akademie der Naturforscher* founded in 1662 as the *Academia naturæ curiosorum*, which was at first devoted to the study of the medical sciences and now covers the sciences generally. The academy has no permanent location, except for its library in Dresden, and its seat changes with the home of the president for the time being. The *Königliche Akademie der Wissenschaften* was established in Berlin in 1700 by Frederick I on the suggestion of Leibnitz, its first president. It was reorganized after a period of decline in 1744 and opened with great ceremony by Frederick the Great (*q v*). The fields of knowledge which are covered by the academy are mathematics, physics, philosophy, and history-philology. The members are divided into ordinary, foreign, honorary, and corresponding. Transactions and proceedings are published. To the credit of this academy fall the publications of the *Corpus Inscriptionum Græcarum*, *Corpus Inscriptionum Latinarum*, *Corpus Inscriptionum Atticarum*, the works of Aristotle, and the *Monumenta Germaniæ Historica*, all works which can be better undertaken by an institution having some continuity than by an individual. The *Königliche Gesellschaft der Wissenschaften* was established at Göttingen in 1751 and reorganized in 1893. It consists of two classes, — mathematical-physical and philological-historical. At Munich there was founded in 1759 the *Königliche Bayerische Akademie der Wissenschaften* which devotes itself to mathematical-physical, philosophical, and historical studies, although originally founded for the last only. The *Königliche Sächsische Gesellschaft der Wissenschaften* at Leipzig was established in 1846 and incorporated with itself the *Fürstlich Jablonowski-Gesellschaft der Wissenschaften* (founded

in 1768) for the study of mathematical-physical and historical-philological subjects. There are further the academies which arise out of the connection in modern times between the arts and sciences, e g the Academy at Heidelberg (f. 1909), and the Kaiser-Wilhelm Academy in Berlin (f. 1910). F. M. S.

**GERMANY, EDUCATION IN THE COLONIES OF** — The colonial possessions of Germany by their position and natural conditions of soil and climate represent strategic rather than commercial value, and the Home Government has no motive for educational efforts in any part of these possessions, comparable, as regards scope and system, to those maintained by the British, or even by the French governments in their foreign dependencies

Beginning with Togoland on the slave coast of Upper Guinea, the German colonies comprise a succession of "spheres of influence" bordering on the ocean-washed coasts of West, Southwest, and Eastern Africa, together with groups of small islands in the Pacific Ocean, and the port town and district of Kiau-Chau in the Shantung province of China. With the exception of the last named, the conditions of German occupation are practically the same in all the colonies. At the seat of government reside the imperial governor and his staff, military posts and courts of justice mark the principal places, and at these points center the schools, government and missionary. These are all educational influences as well as direct incentives to progress. Native interpreters are needed for the governor's service, natives are trained for the military and police corps,

and are subject to criminal processes in the courts, and native teachers are employed in the schools. Thus individuals selected from the mass of rude tribal peoples become familiar, in some slight measure, with the institutions of orderly society. In the East African colonies the German government encounters strong Mohammedan forces, and consequently formal education becomes a matter of serious importance. An effort has here been made to establish compulsory school attendance in restricted measure.

It was undoubtedly the impulse of commercial rivalry that prompted the colonial enterprises in which Germany engaged in the last quarter of the nineteenth century, but neither Africa nor the Pacific islands have so far yielded large returns for business energy or capital. Meanwhile the military advantage of these possessions has become more and more evident. Science has also been brought to the aid of adventure in efforts for utilizing the natural resources of these lands, constructing roads, and supplying commercial facilities, these late efforts are giving industrial aim to the schools that have been established under German influences. The following statistics and context summarize the main particulars relative to the educational work in the several colonies.

## SCHOOL STATISTICS AFRICAN POSSESSIONS

COLONY	POPULATION			GOVERNMENT SCHOOLS		MISSION SCHOOLS	
	Date	White	Native	No	No of Pupils	No	No of Pupils
Togoland	1909	330	1,000,000	2	275	150	9057
Kamerun	1909	1127	3,000,000	4	2200	—	19,000
German South-west Africa	1909	13,791	178,000	11	377	—	3000
German East Africa	1909	3387	1,000,000	—	3821	—	16,500

The German possessions in the Pacific Ocean comprise two groups of islands. to the first group belong, German New Guinea including Kaiser Wilhelm's Land, Bismarck Archipelago and the small adjacent islands, Caroline, Pelew, Marianne, Solomon, and Marshall; the second is the Samoan group including Savau and Upolu. The estimated native population of the two groups is about 450,000, the non-native colored population, mostly Chinese, numbers about 2000, the white population, chiefly German, about 950. Missionary societies, both Protestant and Roman Catholic, are active on all the islands. The Samoan group was formerly under the joint protectorate of Great Britain, the United States, and Germany, but was ceded entirely to the latter power by the Anglo-German agreement of Nov. 14, 1899, ratified the following year by the United States. As a

result of the prolonged relation with Western Powers, the natives of these islands have been Christianized and are very receptive subjects of missionary instruction. A German government school with about 90 pupils is maintained on the island of Upolu, and in 1909 nearly 9000 pupils were under instruction in missionary schools of the two Samoan islands.

The seizure of Kiau-Chau by Germany in 1897, and the subsequent transfer of the town, harbor, and district to that Power by treaty, were events of great importance in the movement which is gradually transforming the Orient. The entire area of the German Protectorate is 200 square miles exclusive of the bay, which is also about 200 square miles in extent. The civil organization, established before the German arrival, comprises 33 townships. The native population of Kiau-Chau is estimated at 120,000, and the European at about 1200, of whom 1000 are Germans. This number does not include soldiers. At Tsingtau the government has established a college for which elaborate plans have been formed. Two departments are provided for, namely, a preparatory school and a school of science. The preparatory school course extends over six years, taking young Chinese of at least thirteen years of age. These students must have had a good Chinese education and be qualified for the lower classes of high schools. A certificate relative to his qualifications must be submitted by the scholar seeking admittance, obtained after examination, which is indispensable, before the Chinese examiner at Tsinan and the inspector of studies of the college at Tsingtau. Knowledge of the German language and modern sciences is not required for the preparatory school, but if newly entering scholars have such knowledge, they will be admitted to the higher classes. An examination is held before graduation from the preparatory school, which must be passed in order to obtain admission into the higher - second department.

The school of science consists of two divisions (1) A department of law and political science, and (2) a technical department, including natural history. The program of the first department comprises international law, general state and administrative rights, state laws, railway, mining, and maritime law, political economy, finances and comparative cases of real property. The general outlines of a process or suit and the features of police administration are also included in the course.

In the technical department there are laboratories for chemistry, physics, electricity, mineralogy, and geology, machine building, mining, etc. Students of the higher college are at liberty to choose their vocations, but must then strictly comply with the schedule. The students of the first term class admitted are expected to remain at college for four years, but, later, discrimination will be made

when the students enter, according to their knowledge of the German language, so that the courses will occupy the following periods: Legal course, three years, forestry, three years, building, two years, technical, four years.

The philosophical course will be taught by Chinese teachers, a medical branch is also projected, and a subcourse will be given in gymnastics, music, and art. The minimum age for the school of science is twenty years, and a good knowledge of the preparatory courses is essential to admission. If a student wishes to join the school of sciences without having attended the preparatory school, he must first pass an examination in both Chinese and Western sciences, including the Chinese and German languages.

The present staff comprises twelve German tutors and ten Chinese teachers and interpreters, as the number of students grows the staff will be increased. A translation office will be opened in conjunction with the college to prepare the necessary material. Arrangements have been made by the managers of the German-Chinese high school to open a free course of lectures on popular scientific subjects, illustrated with pictures and experiments, for the benefit of the foreign residents. Besides these lectures, an evening course in the Chinese language and script, as far as necessary for daily use, will be given for the benefit of the German community.

A colonial department was organized in the Foreign Office at Berlin in 1890, and in 1899 a colonial school was established at Witzenhausen, near Gottingen, with the express purpose of preparing practical farmers, planters, stock-raisers, and fruit growers who may be inclined to settle in some one of the German colonies. In all the colonies, graduates of the school are found to-day acting as business managers for German trading companies, owners and managers of plantations, clerks in the government service, etc. The course of the colonial school lasts two years and is so arranged that the theoretical instruction comes in the winter and the practical instruction in the summer. The subjects chosen for lectures are those which will add to the pupils' knowledge of tropical plants and agriculture and of colonial enterprises and politics. The studies include such branches of learning as chemistry, botany, and physics. The institution is well supplied with laboratories and has a large farm and gardens and wood land for the study of forestry, vine growing, etc. The trade shops of Witzenhausen are also open to the students for practical instruction.

It is noticeable that while graduates of the colonial school are found in the African and Asiatic colonies, they prefer the German settlements in the new world, especially in Brazil, Argentina, and Chile, and their expert knowledge and skill are proving of immense value in the commercial and industrial development of those countries.

The growing importance of German colonial enterprise is illustrated in the proposed plans of the new university at Hamburg, which shall include a faculty of colonial science. This faculty will constitute the distinctive feature of the new institution

GERRY SCHOOLS — See HUMANE EDUCATION

**GERSON, JEAN CHARLIER** (1363–1429) — Teacher, theologian, and chancellor of the University of Paris, born at Gerson, educated very probably at Rheims, and studied at the College of Navarre in Paris. He early devoted himself to theology, and obtained the degree of doctor in that subject. At the early age of thirty-two he became Chancellor of the University of Paris in succession to his friend and teacher, Peter d'Ailly. His standing as a theologian was high, and he soon gained the title of *Doctor Christianissimus*. Breaking from the scholasticism and dialectic methods of his day, his writings show a return to source material and the Church fathers, and a good knowledge of the classics, while his philosophy was nominalistic colored by mysticism. At the Councils of Pisa and Constance he was an important factor, and his general influence was considerable. He preached to the people in the vernacular, mainly on questions of practical morality, and took a great interest in the young students of Paris, where he tried to introduce some sort of guidance and a moral spirit among them. In a letter he recommended to such a student a study of Greek and Latin works for their content, and for style. As a teacher himself, he looked to Quintilian for the ideal in his field. His chief educational work was the *Tractate on Leading the Little Ones to Christ* (*Tractatus de Parvulis tradendis ad Christum*), which, as is indicated in the title, concerns itself wholly with religious and moral education. The work, which has as its text Mat. xix, 14, is divided into four parts, each with its own text. (1) The necessity and means for educating the young for reverence of God, religion, humanity, and civilization on a basis of habit (La. iii, 29). The means are sermons, private admonition, discipline, and the confessional. (2) On those who offend young children by bad examples (Mat. xviii, 16). (3) On the great service performed by the religious teacher (James, v, 20). (4) Self-defence and

apology (Gal. vi, 1). The last ten years of his life he spent in a convent of Cælestine monks and devoted much time to teaching children.

**GESNER, CONRAD** (1516–1565) — Called by Hallam "a man of prodigious erudition." He was born at Zurich. His parents being unable to educate him, he was befriended, housed, and educated by Amman, the professor of rhetoric, for three years. He resolved to travel, and entered the service of Capito, a Hebrew scholar, at Strassburg. After further travel, he was placed at the head of a school at Zurich. After studying physic, he resigned his school teaching, and, having had a small pension allotted him, he set to work at reading the Greek physicians. For a time he was professor of Greek at Lausanne, and was professor of philosophy at Zurich for the last twenty-four years of his life. Gesner wrote his *Bibliotheca Universalis* in 1545. This was a catalogue of books in Latin, Greek, and Hebrew, and gave criticisms and specimens of many of the works cited. He wrote a continuation of the work in the *Pandectæ Universales*, 1548–1555. These two works attempted to do for general literature what the Digest of Justinian had done for Civil Law. Thus Gesner's books are of the greatest value as a bibliographical encyclopedia of literature up to his times. In 1555 he published *Mithridates de differentiis linguarum tum veterum, tum quæ hodie apud diversas nationes in toto orbe terrarum in usu sunt, observationes*. This is the first great modern book on comparative philology, and attempts a characterization of all ancient and modern languages from the Ethiopic down to the gipsy language. Gesner also wrote the *Historiæ Animalium* published in 1551–1556, containing a critical account of all that had been written and done on zoology by his predecessors. His *Icones Animalium* is a volume of woodcuts and names only. As a naturalist Gesner emphasized the method of personal observation instead of relying on the observations of the old classical writers, though he did a great deal in promoting the close study of those writers. He planted a botanic garden for his observation and experiments. He formed a museum in connection with his professorial post and obtained contributions of some specimens from most parts of Europe. He made the ascent of Mont Pilatus near Lucerne and examined all the specimens he could find there, in spite of the superstitions concerning the mountain. He visited patients in Zurich at the time of the plague and devoted himself to the study of the best cures, but he was overtaken by it and died in his Museum in 1565.

He was the greatest encyclopedist of the Renaissance

**GESNER, JOHANN MATHIAS** (1691–1761) — Prominent philologist and reformer of higher education in Germany; was born the son of a pastor in the small city of Roth in Franconia and received his early education at the gymnasium in Ansbach. In 1610 he went to the university of Jena, in 1715 he was appointed teacher of the gymnasium in Weimar, in 1729 he accepted a call to the principalship of the gymnasium in Ansbach, but finding that this position did not allow him sufficient leisure for his literary activity, he left it the following year and became the head of the old *Thomas-schule* in Leipzig. He reestablished the reputation of the school by restoring the study of the classics, by enriching the course of study, especially through the emphasis laid on mathematics, and by improving the discipline. In 1734 he was called as Professor of Rhetoric to the newly established university of Göttingen and remained there until his death. He lectured on Latin and Greek literature and on classic archæology, but, at the same time, kept up his strong interest in pedagogy. He was the inspector of the Brunswick gymnasiums and conducted, from 1738 on, a philological seminar in which candidates for the teaching profession received a general education together with theoretical and practical training in pedagogy. For this purpose he wrote his *Primæ linæe isagoges in eruditionem universalem* (*Outlines of an introduction to general education*, particularly to philology, history, and philosophy), which appeared in 1760. As early as 1715, he had written his *Institutiones rei scholasticæ*, a treatise on education, which shows the influence of the ideas of Ratke, Comenius, and Locke.

Gesner's educational activity marks an epoch in the history of classical education in Germany. He is the founder of that great movement in German education which is known as *Neo-Humanism* (*qv*) and which controlled the aim and methods of the most influential of the higher schools, and through them the educational ideals of the leading classes of the nation, down to the last quarter of the nineteenth century. He revived the study of Greek, which in Germany at that time had been almost totally neglected, and insisted on the study of the classics for the sake of their great thought content and their ethical and æsthetic value. He believed in arousing in the pupil a pleasurable interest in his work, and, for this reason, he advocated the teaching of the elements of Latin

through usage only, and without the help of formal grammar. In this way he was a forerunner of Basedow and of the modern reformers of foreign language instruction. Next to the study of the classics, he emphasized instruction in the mother tongue, in French, mathematics, natural science, history, and geography. Gesner's educational views were backed by a rare combination of great erudition, not only in philology but in several other fields of knowledge, with a long practical experience in teaching and fine pedagogic tact. Through his connection with the Brunswick schools and his training of teachers, he had constant opportunities of testing the actual operation of his theories in practice. It is owing to these favorable circumstances, and to the fact that his work was carried on by such brilliant successors as Ernesti (*qv*) in Leipzig and Heyne (*qv*) in Göttingen, that the movement initiated by Gesner acquired such a great and lasting influence on the higher education of Germany.

Among the writings of Gesner, besides the works already noted, may be mentioned his various editions of Latin authors, as well as his selections from Cicero, Pliny, and from Greek authors (*Chrestomathia Ciceroniana* 1716, *Pliniana* 1723, *Græca* 1731), the last of which contributed greatly to the improvement of the study of Greek in Germany, his *Thesaurus* of the Latin language, published in 1745 in four volumes, and his *German Essays* (*Kleine Deutsche Schriften* 1756), which contain much of pedagogic value. **GHERARDO OF CREMONA** -- A distinguished scholar and teacher of mathematics in the twelfth century. He was born in 1114 at Cremona, in Lombardy, and died there in 1187. He is known chiefly for his work in astronomy, which included several translations from the Arabic, the *Almagest* (see **PTOLEMY**) among them. D E S

**GIBBS, JONATHAN C** (1831-1874) -- A colored educator, educated at Dartmouth College (graduating in 1852) and at the Princeton Theological Seminary. He was in charge of the educational work organized by the Presbyterian church among the freedmen (1863-1868), secretary of state in Florida (1868-1872), and state superintendent of public instruction in Florida (1872-1874). W S M

**GIDDINESS** -- See **DIZZINESS**

**GIESSEN, THE GRAND DUCAL HES-SIAN LUDWIG UNIVERSITY OF** -- The University of Giessen was founded by Landgrave Louis V, the Faithful, in the year 1607, and owes its origin to the religious conditions of the period. (See **GERMANY, EDUCATION IN**, section on *Universities*.) Giessen, from its inception, possessed the character of a university, although in the beginning the theological faculty was by far the largest and most renowned, the institution being known far and wide as a Lutheran stronghold. To this circumstance may be attributed the fact that at the outbreak of the Thirty Years' War Giessen was one of the most frequented universities in the whole of Germany, being exceeded in size probably only by Leipzig and Jena. As a direct result of political changes, the university was transferred to Marburg in 1625, a religious controversy at the latter institution twenty years previous having led to the secession that was responsible for the organization of a university at Giessen. At the close of the war, another political transfer brought about the reestablishment of the institution at Giessen, and from that time to the present day the university has had an honored, albeit somewhat modest existence.

A faculty of political economy was established at the university in 1777 and may be regarded as the forerunner of the faculties of political science, but it was disorganized eight years later. In 1829 a school of forestry was established as a branch of the university, and from 1837 to 1875 Giessen also possessed a technical school (at Darmstadt since 1877), both departments being included in the faculty of philosophy. This fact is worthy of comment, as the schools of technology are not affiliated with the universities in Germany. The faculty of medicine includes a college of veteri-

nary medicine, which is the only school in Germany to award the degree of Dr. Med. Vet. From 1830 to 1859 Giessen also supported a Catholic theological faculty.

A new library building was completed in 1904, having been erected at a cost of \$125,000, it contains over 230,000 volumes and over 100,000 dissertations and programs. The annual university budget amounts to about \$375,000. Giessen is one of the smallest of the German universities in point of attendance, there being 1249 students enrolled in the winter semester of 1910-1911, of whom more than half are registered in the faculty of philosophy, this being followed by medicine, law, and theology, in the order named.

Among former teachers of the university may be mentioned the celebrated jurist Rudolf von Jhering, and the renowned chemist Justus von Liebig, Robert von Schlagintweit, the explorer, served as doцент at Giessen from 1863 to 1885. R T, Jr

**GILBERT, SIR HUMPHREY** (1539-1583)

-- The navigator and stepbrother of Sir Walter Raleigh. In c. 1572 he devised a scheme for "the erection of an Academy in London for the education of her Majesty's Wards and others the youth of nobility and gentlemen," which was edited from the Lansdowne Ms. by Dr. F. J. Furnivall for the Early English Text Society in 1869. Gilbert bewails the fact that the wards of the Crown were often in the hands of those of evil religion or insufficient quality, and since these wards were chiefly resident in London, he proposes that an Academy be erected and suggests not only the subjects to be taught therein but also the salaries to be paid to the teachers and ushers. A new type of education was proposed, based on a curriculum differing from that of the humanistic schools of the day. Milton's *Tractate* shows a remarkable similarity to Gilbert's work. Masters were to be engaged to teach Latin, Greek, and Hebrew, although a sufficiently important place is assigned to the vernacular, for "in what language soever learning is attained the appliance to use is principally in the vulgar speech as in preaching, in parliament, in council, in commissions and other offices of common weal." Readers were to be appointed for moral philosophy to read "the political part thereof", for natural philosophy, for mathematics to deal with military art, cosmography, astronomy, and practical navigation. A doctor of physic was to teach physic, chirurgery, and medicines, and was to have a garden and simples. Civil

law, divinity, and common law were each to have a reader. Provision was to be made for the teaching of modern languages, dancing, heraldry, defence, horsemanship, strategy, and tactics.

The arrangements for the library are particularly interesting. The keeper is allowed £26 a year. After every mart he "shall cause the bringers of books into England to exhibit to him their registers, and thus to have first choice of books to buy. For the buying of books, etc., for the library £40 was to be allowed. But in addition it is to be noted, "All printers in England shall be forever charged to deliver into the library of the Academy, at their own charges, one copy, well bound, of every book, proclamation, or pamphlet printed." The treasurer's salary was to be £100. The chief governor was to be the master of the wards, assisted by the rector who was to have personal supervision over the pupils. The public readers of arts and common laws were to publish some new book every six years, and every three years to issue a translation of some good book. F. W.

**GILCHRIST, JOHN BORTHWICK** — See GILCHRIST EDUCATIONAL TRUST

**GILCHRIST EDUCATIONAL TRUST** — An institution established by the will of John Borthwick Gilchrist (1759-1841), a servant of the East India Company and an orientalist. He was professor of Hindustani at London University and took an interest in educational and philanthropic efforts, being associated with George Birkbeck (qv) in some of his work. He left his property to trustees for "the benefit, advancement, and propagation of education and learning in every part of the world so far as circumstances will permit." He left every arrangement to the discretion of his trustees. The will was the subject of litigation which lasted twenty-five years, and only the fortunate circumstance that part of the property was on the site of Sydney, Australia, rapidly increasing in value, secured any means for the trustees to proceed with their work. The trustees adopted the principle of doing pioneer work in promoting education and learning where other efforts were not being employed. In this way numerous movements have been started, and as soon as they have been taken over by other bodies, the Trust has diverted its support to some new object. Thus, scholarships to aid Indian students to study at English universities were established until the work was taken up by the government and universi-

ties were erected in India. Colonial scholarships were also instituted. When Girton College and other institutions were established for the higher education of women, scholarships were provided as well as in training colleges for secondary school teachers. Traveling scholarships for secondary school teachers were established for professional purposes. Reports have been published on educational topics in foreign countries including Educational Systems of Sweden, Norway, and Denmark, French Secondary Education, The Teaching of Literature in Girls' Schools in Germany, Manual Instruction in France and Switzerland; The Teaching of Geography in Switzerland and Italy. When the Board of Education undertook the *Special Reports*, the Trust discontinued the traveling scholarships, just as the system of exchange teachers between England, France, and Germany was begun by the Trust until taken over by the Board. University Extension, the Workers Educational Association (qv), the National Home Reading Union (qv), and the Recreative Schools Association have also been assisted by the Trust. At present the Trust money is being used to encourage a system by which young teachers may be afforded opportunities of spending some time in the classrooms of expert and more mature colleagues. A scheme is also on foot for the establishment of a school of Oriental Languages to commemorate the work of the founder. The remarkable success of the Trust has shown the importance of freedom in the management of Trust funds for public purposes. More good work has been accomplished and more success has been achieved in this way than would have been possible under the restraint of the "dead hand" of regulations and provisions, which only too often hamper such bequests, not only in England but in America. The Right Honorable Lord Shuttleworth is at present chairman of the Trust, which has its offices in London.

#### GILDS, MEDIEVAL, AND EDUCATION

— To conceive of the gild as the technical school of the middle ages is to realize only very imperfectly its importance for the history of education. The gilds of merchants and craftsmen which regulated commerce and industry from the eleventh and twelfth centuries onward were only species in a great genus which embraced such widely different institutions as the Universities, the Inns of Court, the Colleges of Physicians and Surgeons on the one side, and the humblest parish burial club or rural cooperative society on the other. The religious fraternity supplied the only available form and sanction for every kind of free association, whatever its aim — political, social,

economic, recreative, educational, religious. In its main aspect it may be regarded as the main instrument in the formation of that series of middle classes by whose efforts the principle of self-government was first realized in the narrower sphere of civic life and thence transplanted to the wider sphere of the national state.

Although it is generally confined to the professional and technical aspects of this development, the term "education" applies in a large sense to the whole process of class formation, and a few words may be said as to the social and political education afforded by the guilds. Socially their primary function was to facilitate a transition from the tie of kinship to that of a fellowship based on neighborhood or a common profession. The Saxon guilds of thanes which Maitland has likened to a "county club", the "frith guilds" of London and the Knights' guilds which in some cases perhaps formed the first nucleus of free civic association, all served this purpose and are connected by it as one continuous social development, both with the merchant and craft guilds and with the parish guilds in town and country. By their instrumentality the process described by Fustel de Coulanges as taking place in the city state of antiquity was carried a stage further. What the fiction of adoption and the artificial widening of the ancestral cult were to the earlier phase of civic expansion, the more attenuated fiction of fraternity, and the foundation of cooperative chantries were to the medieval city. Closely connected with this was a more consciously educational development. The wealthy city guilds took over the halls of feudal magnates and cooperatively emulated their style of life. They feasted kings, and drew nobility, gentry, and clergy into their honorary membership, and were thus one of the main agencies in removing social exclusiveness and in transmitting social manners and ideals from a narrower to a wider circle.

In the political education of the middle ages the guilds played an unique part. They were the main channels through which new classes of the population were drawn into the field of political activity. Their internal affairs furnished an excellent training in self-government and administration, whilst their intervention in municipal and occasionally in national politics gave their ambitious members a wider scope for their powers. The disputes that have arisen as to the part played by the guilds in the earliest phases of civic organization turn upon questions of constitutional form and leave untouched the primary importance of the guilds as generators of political force and organs of political change. In many leading cases at least it is highly probable that the guilds of the twelfth century had as large a share in molding the earlier patrician rule in the cities of Western Europe as the craft guilds of the thirteenth and fourteenth centuries had in trans-

forming it. The proceedings of the guilds, as such, were secret, but they provided periodical opportunities for freely debating questions of policy or of principle, and there can be little doubt that towards the end of the fourteenth century, when the guilds became more numerous and active both in town and country, they often served as centers of political, social, and religious propaganda.

Turning now to education in the stricter sense it is well to emphasize the fact already noted that the greater part of the organized higher education of the middle ages was based on a social structure provided by guilds. "The rise of the universities," says Rashdall, "was merely a wave of that great movement towards association which began to sweep over the cities of Europe in the course of the eleventh century" (See UNIVERSITIES). The federated guilds of scholars or teachers or both, of which the universities were composed, performed the same functions in regard to the higher education of the professional classes as the later guilds performed in regard to the technical education of the merchant and the craftsman (See DEGREES, INCEPTION). The completed guild structure of a London livery company towards the close of the fifteenth century is closely analogous to that of one of the Inns of Court (*q.v.*) or one of the Oxford colleges of the same period.

A link between the universities and the guilds is furnished by the civic corporations of the learned professions. The notaries formed one of the greater guilds of Florence, and probably the regulations imposed by the civic authorities of London in the thirteenth century on pleaders and attorneys were drawn up by a professional guild. In fifteenth-century London the professions of medicine and surgery received from the city a set of ordinances which placed them under the rule of a Rector who must be a Doctor of Medicine, a Master of Arts and Philosophy, or a Bachelor of Medicine of long standing, and the last-named degree was only to be accepted as a temporary makeshift. The guild insisted on previous graduation for full membership, imposed examinations in medicine and surgery, and provided a hall for reading and disputation. Later on, in the seventeenth and eighteenth centuries, the Barber-Surgeons of London, Paris, and Edinburgh provided regular demonstrations in anatomy for the instruction of their members. The London guild of Apothecaries has retained its examining functions down to the present day. (See PHARMACEUTICAL EDUCATION.)

Whilst the medical and surgical guilds were thus able to delegate many of their educational functions to the universities, the guilds of merchants and craftsmen were the sole repositories of the traditional lore of their several callings. It is very probable that they were the main channels by which that lore was transmitted from the East to the West and from the later

days of the Roman Empire to the earlier middle ages Dr L M Hartmann has recently established a strong case for the continuity of the gild tradition at Rome and Ravenna. The style of the earliest cathedral builders has been traced continuously back to the school of "Comacine" masters, whom the Lombards found working in North Italy. The dedications of the gilds of the five fundamental medieval handicrafts afford corroborative evidence which has been hitherto overlooked. The patron saints of the masons — the Quatuor Coronati — were Roman martyrs of the third century, those of the shoemakers — St Crispin and St Crispinian — are said to have been martyred at Soissons at the same period. St Aubert, the patron saint of the bakers of Flanders and Scotland, was Bishop of Cambrai and Arras in the seventh century. St Eloi, universally venerated by the smiths of the middle ages, was a goldsmith of Limoges who became a missionary Bishop at Noyon under Dagobert. But perhaps the most interesting case is that of St Severus, a woolcomber, who was Bishop of Ravenna just before the fall of the empire and whose body was afterwards carried, first to Mainz — the place of the first recorded weavers' gild in Germany — and thence to Erfurt, another weaving center, and who is subsequently found as the patron saint of weavers throughout the Netherlands and Scotland. A similar significance attaches to the spread of the cult of St Nicholas of Myra, the patron saint of Levantine commerce and navigation, which is exactly contemporaneous with the settlement of a hitherto largely nomadic trading class and the rise of the merchant gild. There are early churches of St Nicholas in close connection with the ports or markets of London, Bristol, Yarmouth, Newcastle-on-Tyne, Liverpool, Ghent, Brussels, Utrecht, Berlin, Frankfurt, Leipzig, Hamburg, Prague, Stockholm, Bergen.

It is thus probable that the most important educational service of the gilds was removed before their recorded history begins. In the later period, inaugurated by the grant of royal charters or civic ordinances in the twelfth and thirteenth centuries, the growth of the system of apprenticeship is the central feature of gild history from the educational point of view. The earliest extant records of apprenticeship are private contracts between individuals which stipulate for a premium or certain years of service in return for specified teaching. The authorized regulation of the conditions of apprenticeship by the gilds begins in London, Paris, and elsewhere in the last quarter of the thirteenth century. The urban population was then rapidly increasing. Division of labor was giving rise to new trades for which the craft gild furnished a ready organization, and during the two following centuries a steady stream of rural labor was drawn by this agency into the channels of a higher technical training.

The education provided by the gild rested entirely on a domestic basis. As a rule the master craftsman might teach his trade to as many sons as he pleased, but could only have one other apprentice who received board and lodging, clothing and discipline as one of the family. In entering the new household the apprentice passed under the protection of the gild which revised the terms of his contract, furnished a court of appeal against ill usage or defective training, and guaranteed the ultimate attainment of mastership. This produced uniformity within each craft, but the variations of usage between different crafts and different cities remained very wide throughout the middle ages. In Paris the cooks required two years' service, the carpenters four, the chandlers six, the embroiderers eight, the goldsmiths ten. A seven years' apprenticeship, which had become universal amongst London crafts, was adopted as the national standard in the sixteenth century. On the continent a much shorter period of from two to six years was supplemented by the requirement of from three to five years' travel in search of fuller experience. Some of the Rhine cities were much frequented by journeymen as the finishing school of their several trades.

Besides regulating access to the only technical school, the workshop, the gilds largely determined the nature of the instruction thus afforded, not only by an official examination of the aspirants to mastership, but also more effectively by the regular inspection of their trades, backed by civic authority, in which the collective technical conscience of the gild was brought to bear on the methods of the individual craftsman. False work and bad materials were seized and judged by juries of experts. In some crafts, *e.g.* the goldsmiths, the gild affixed its stamp to sound work, in others, *e.g.* the blacksmiths, the pewterers, and even the bakers, each master must have a mark of his own, whilst in the cloth manufacture it became usual to insist on inspection and official sealing at each stage. Technical rules multiplied under the control of the gilds and were afterwards in many cases codified in national legislation. The Act of 1603-1604, which prescribes in fifty-two elaborate sections the industrial technique to be followed by the English leather trades, is an interesting illustration of the cumulative power of gild tradition. It is very difficult to appraise justly the educational value of this tradition. In its later phases, when we know it best, it was almost wholly a hindrance to industrial progress. It was in the earlier and less recorded phases that the gilds performed their real educational service by disciplining crude labor, checking dishonest impulses, and gradually forming a professional sense of honor. But even then the gild's powers of search were often used to exclude the competition of foreign wares. Later on, when the craft gilds acquired pre-

dominance in city government, their policy as embodied in their ordinances, their methods of inspection, and their regulation or apprenticeship exhibited a narrower spirit of corporate egotism. The two opposite abuses to which the system of apprenticeship is liable -- undue restriction as a means of limiting the number of masters and entire absence of restriction as a means of exploiting youthful labor -- both became common in the fifteenth century.

The ordinances of the majority of guilds at the close of the middle ages exhibit a compromise between these conflicting tendencies. New masters are often forbidden to take any apprentices for several years, and then restricted to one, whilst those who sit on the governing body may take two, and those who have held the highest office three. By this time the entrance to mastership had likewise become restricted, partly by the growth of industrial capital, but also by the imposition of artificial conditions. Foremost among these was the institution of the masterpiece, which did not become widespread till the sixteenth century. Originating in simple tests of competent workmanship this developed into the imposition of a task sometimes occupying many months and requiring the use of expensive material besides the payment of heavy fees to the official examiners. The extant rules for the execution of the masterpiece -- which in the case of a wide range of Paris crafts cover a period of four centuries -- form a valuable contribution to the history of technical education. A jury of scribes examined candidates in calligraphy, orthography, and casting of accounts. The printers and booksellers required a knowledge of Greek and Latin, the masterpiece of the pinners was a thousand pins, of the shoemakers a pair of boots, three pairs of shoes, and a pair of slippers, of the butchers the dressing for sale of the carcasses of a cow, a calf, a sheep, and a pig. But in many cases much more elaborate tests were prescribed or were left to the discretion of the guild authorities who deliberately used them to exclude candidates from the mastership. At the same time the sons of masters and those who could pay a large entrance fee were exempted altogether or subjected to a nominal test. Whilst, therefore, the educational functions of the guilds attained their most explicit and impressive form in the masterpiece, they were simultaneously ceasing to exercise an appreciable influence on the main course of industrial development which by this time was escaping from the corporate restrictions imposed in the older urban centers and seeking a freer environment in the country. However regrettable, it was no doubt natural that the pioneers of the next phase of industrial progress and especially the inventors of labor-saving machinery should have found their chief obstacle in the handicraft traditions of the guilds. (See APPRENTICESHIP AND EDUCATION, INDUSTRIAL EDUCATION) G U

The guilds were, however, more intimately associated with school education in England. Many guilds maintained one or more priests to minister to the members of the fraternity, the practice arose for these priests to keep school for children of members or of the whole town. In time money was left to guilds for the express purpose of engaging a clerk to keep school, elsewhere the guilds paid the schoolmaster out of their funds. Thus at Barnard Castle the Gild of Trinity was "founded and endowed with certain lands, by gift of the brethren and other benefactors of the sons of ancient time to find a priest to say mass and to keep a free grammar school and a song school for all the children of the town." Of 33 guilds investigated by Leach, "excluding the Craft Guilds of London and Shrewsbury, and the Merchants' Gild at York, 28 kept grammar schools, and to them may be added the Drapers of Shrewsbury, who kept a grammar school, while the Mercers of London were trustees for three schools mentioned, and the Goldsmiths for two." In many instances the guild corporations were appointed as trustees of schools and with them were vested the right of appointing or dismissing the schoolmaster, the superintendence of repairs, the school property, the admission of pupils, the drawing up of statutes for the better government of schools, or appointing boards of governors for schools. The Skinners' Company of London became trustees for Tonbridge School in 1552 with power to draw up statutes for the school, and the practice grew up for the governors to pay an annual visit to the school. With the decay of the guild system most of the schools maintained or supervised by the schools became private endowed schools, while only a few schools in London have remained under the control of guilds, e.g. Merchant Taylors' School, Stationers' School, and the Mercers' School.

Of recent years, some of the wealthier London companies have devoted large sums to the endowment of technical and university education.

**GILDS, TEACHERS'** — These were associations which arose in the sixteenth century to protect those teachers of primary subjects who had municipal recognition against the competition of the wandering scholars, dame and hedge-schools (*Winkelschulen*). Such organizations were confined to Germany, though at least one is found in Holland-Harlem. There is definite information bearing on the gilds in Munich (1564), Nuremberg (1613), Frankfurt-a.-M. (1613), and Lubeck (1653), while they also existed in Augsburg, Landshut, Bamberg, Stuttgart, Tubingen, Urach, and Brunswick. At Lubeck a second gild of teachers of reading and prayers was also organized. Their organization was similar to that of other gilds, which were practically on the decline when the teachers organized. A period of apprenticeship, varying from three to nine years, and beginning with the sixteenth or eighteenth year, was imposed. An examination had to be passed to become a journeyman or assistant teacher. The assistant could be employed for pay by a master and could also give private lessons, part of the proceeds going to his master. When a vacancy occurred in the gild, it was filled by the oldest assistant on proving his ability, usually by writing out, with great flourishes a signboard, a Latin motto, e.g. *Patientia omnia vincit*, or a Biblical quotation, and the master's name formed the content. The gilds struggled with difficulty against competition but without success, in spite of protests to the municipal councils, which supervised and inspected their schools. On the whole their influence was baneful, they kept down the number of schools by increasing the number of pupils in the few favored institutions without adding to the accommodations, the qualifications for membership were not always strictly adhered to, the sons, widows, or daughters of deceased members were sometimes allowed to continue schools without being required to go through the regular routine. Materially the gilds did not improve the position of their members, for many had to supplement their slight income by alms. One advantage, however, did accrue, members of the gilds were *ipso facto* citizens. The gilds lingered on ineffectually until the end of the eighteenth century. The Munich gild was finally dissolved in 1801, the capable teachers being incorporated into the state system. At Nuremberg, the gild was driven out in 1818 on the introduction of paid teachers, while at Lubeck the last was heard of the gild in the same year.

**GILL, ALEXANDER** (1565–1635) — Headmaster of St Paul's school, London, from 1608 till 1635. He had John Milton as pupil in the school from 1620 to 1625. Gill continued the tradition of Mulcaster's (*qv*) interest in the study of the English language as shown in Mulcaster's *Elementarie* 1582, and in 1619 published the book for which he is best known — *Logonomia Anglica, qua Gentis Sermo facilius addiscitur*. He advocated the phonetic spelling, and suggested a reform of the alphabet with that purpose, by introducing the two Anglo-Saxon signs for *th* and other Anglo-Saxon signs, together with dots over the vowels to represent their various sounds, he gets his adequate alphabet. In the feeling of pride in our old Saxon tongue Gill ranks as a pioneer. The most interesting section of the *Logonomia Anglica* is the part devoted to Syntax, where he begins to treat of the figures of speech. Following on the lines of Abraham Fraunce (*qv*), Gill quotes from English writers to illustrate the English usage in rhetorical figures. The significance of the book is the establishment of Ramus's method of illustration of rhetorical figures from modern sources, the drawing of attention to the beauties of the English literary writers, and the beginnings of the study of English literature in a school textbook. The curious point must be borne in mind, that Gill's *Logonomia* is written in Latin. Gill's son, also called Alexander (1597–1642), in 1621 became under usher of St Paul's school to his father, and was teacher and friend of Milton. Gill fell in disgrace in 1628, through drinking a health to Felton, the assassin of Buckingham, and belittling the king. Eventually forgiven, he is said to have been an usher in Farnaby's (*qv*) school, and in 1635, succeeded his father as High or Head Master of St Paul's School. He died in 1642, having gained the reputation for great severity in connection with school teaching.

**GILMAN, DANIEL COIT** (1831–1908) — The first president of Johns Hopkins University, and one of the leading influences in American educational development during the greater part of his career. He was born in Norwich, Conn., July 6, 1831, and was of old New England ancestry on both sides. Graduating at Yale in 1852, he pursued graduate studies at Harvard for a year, residing in the home of Arnold Guyot, the geographer, then he spent two years in Europe, where, though an attaché of the United States Legation at St. Petersburg, he found opportunities for seeing and learning much of England, Germany, and France, as well as of Russia. Returning in 1855,

he took an active part in advancing the permanent organization of the Sheffield Scientific School at Yale, and became one of the chief promoters there of the ideas of "the new learning." He was an ardent champion of scientific studies as a means of culture, though he fully recognized the claims of the classical education; and it was precisely this attitude that he afterwards manifested in shaping the character of Johns Hopkins University. He was made assistant librarian of Yale College in 1856, and afterwards librarian and professor of physical geography. During his connection with Yale, which ended in 1872 with his acceptance of the presidency of the University of California, he was one of the chief influences making for progress generally, and in particular for the building up of the Sheffield Scientific School. He was also actively connected with the public school system of Connecticut, in which he introduced important improvements. The University of California, under his presidency, from 1872 to 1875, underwent a most remarkable development, in spite of the obstacles interposed by political interference. He became president of Johns Hopkins University in 1875.

The establishment of Johns Hopkins University in 1876 marks an epoch in the history of education and learning in America, and it is to Gilman that the determination of its character must be ascribed. From the beginning, he set before himself the object of making the new institution a means of supplying to the nation intellectual training of a higher order than could be obtained at existing American colleges and universities, and at the end of a year of travel and inquiry he had gathered, as a nucleus, six professors of eminent ability, under whom, with the aid of younger associates, there was launched, for the first time in this country, a university whose standards and activities were on a level with those of the great institutions of Europe. The establishment of full-fledged "graduate schools," the naturalization of research as a leading element in American universities, and the development on a great scale of scientific and scholarly publications, date from the foundation of Johns Hopkins University. And a singular testimony to the importance of Gilman's influence in hastening this development is furnished by the fact that, although it was not until seventeen years later that funds were available for the opening of the Johns Hopkins Medical School, no other institution in the meanwhile attempted to bring about "the prodigious advancement of medical teaching"—to quote President Eliot— which was there effected under Gilman's guidance, and in accordance with the aim that he had cherished from the beginning.

In 1901 Gilman resigned the presidency of Johns Hopkins. In 1902 he became the first president of the Carnegie Institution, he resigned that office in 1904, but continued as a trustee of the institution until his death.

Throughout his life, in addition to his educational activities, he was deeply and actively interested in public improvement and in practical philanthropic effort, being, in particular, one of the pioneer workers in charity organization and in civil service reform. He succeeded Carl Schurz as president of the National Civil Service Reform League, his connection with the Peabody Fund, the Slater Fund, and the Russell Sage Foundation was of great importance; and he served on many public and semi-public commissions. His contributions to periodical literature were numerous, and he was one of the chief editors of the *New International Encyclopedia*. He wrote a *Life of James D. Dana* and the volume on *James Monroe* in the "American Statesmen" series. He edited the *Miscellaneous Writings of Francis Lieber*, and prepared an edition of De Tocqueville's *Democracy in America*, for which he wrote an elaborate introduction. Two other volumes published by him are *University Addresses* and *The Launching of a University*. He died at Norwich, Conn., Oct. 13, 1908. F. F.

FRANKLIN, FABIAN. *Life of Daniel Coit Gilman*. (New York, 1910.)

**GILPIN, WILLIAM** (1724–1804) — Schoolmaster, author, and artist. He graduated B.A. at Oxford in 1744 and was ordained in 1746. A few years later he took over a boarding school at Cheam, Surrey, which he kept successfully for nearly thirty years and handed on to his son. The school is still in existence under the charge of a descendant of Gilpin. The distinguishing marks of the school were the study of the vernacular, of gardening and business, the boys engaging in practical commerce on their own accounts, the elimination of corporal punishment, replaced by trial by jury and fines which were spent for the general welfare of the whole school, and confidence in and reliance on the boys' sense of honor. As Vicar of Boldre Gilpin took an active interest in the social welfare of his parishioners and gave a number of his pictures to endow a parish school. In 1779 he published *Lectures on the Church Catechism*, which had been prepared earlier for his pupils. His writings consisted of biographies of eminent English Churchmen, including his own ancestor Bernard Gilpin, and descriptions of points of artistic interest in England accompanied with his own sketches.

#### **GIRARD COLLEGE, PHILADELPHIA, PA.**

— An institution founded by the will of Stephen Girard (*qv*) for "poor white male orphan" children, and opened in 1848. The institution was placed in trust of the Councils of the City of Philadelphia, and is now managed by the

Board of Directors of City Trusts. Alexander Dallas Bache (*q.v.*) was appointed the first president and was sent by the trustees to Europe to make a survey of the educational institutions and systems. By one of the terms of the will "no ecclesiastic, missionary or minister of any sect whatsoever" is admitted in any capacity within the premises of the institution. An attack on the will failed in the courts on the ground that the exclusion of ministers was not necessarily an attack on religion or broad religious teaching. Orphan (*i.e.* fatherless) boys are admitted between the ages of six and ten years and receive a training such as will enable them to earn their own living at fourteen to eighteen years of age. The enrollment in December, 1911 was 1491.

#### GIRARD, JEAN BAPTISTE (1765-1850)

— Better known as Père Grégoire Girard, a contemporary and fellow-countryman of Pestalozzi. Born in Freiburg, he attended the Jesuit school there and at the age of seventeen joined the Franciscan Order. He spent his novitiate in Lucerne and thence proceeded to the University of Wurzburg, where he studied theology. When the Swiss government had the reform of public education under consideration, he drew up a plan for primary, secondary, and cantonal schools and a national Swiss university, as a result of which he was appointed secretary to the Minister for Culture and Education, to act as advisor in the Catholic interests. Finding that his advice was rarely sought, he became pastor in Berne (1800-1804), where his broad humanitarian sympathies cut across denominational limitations and endeared him to everybody. He devoted himself mainly to the study of education and was inspired by the efforts of Pestalozzi at this period. His opportunity came in 1804 when he was called to his native city to organize public education. For more than twenty years he strove with great success to reform educational practice and theory. Starting with 40 pupils, the school in 1820 had 400 pupils, and the idea of education became established as essential to public welfare, not only in the minds of most of his fellow-citizens, but also in the surrounding cantons. The school was much visited by foreign observers. But the work of Pestalozzi tended to overshadow that of Girard who aimed to put the master's theories into practice so far as possible. In 1809 he was sent with the commission appointed by the government to Yverdon, and his report on the whole was satisfactory (*Rapport sur l'Institut de Pestalozzi présenté à la haute Diète de*

*la Suisse*). Unfortunately the labors of Girard were suspended by the reactionaries as tending to undermine religion and as being revolutionary, and in 1823 the school was closed. Girard retired to Lucerne, where he devoted himself to writing and recommending educational reform.

Girard was strongly influenced in the direction of the moral and religious end of education. Pestalozzi's work he criticized on the ground that too much emphasis was laid on the intellectual and too little on the emotional and volitional aspects. He accepted the theory of harmonious development as the aim of instruction, but here again he held that Pestalozzi overemphasized the mathematical subjects, which he feared would lead to materialism. Nature study, history, and geography were all to lead to a recognition of God, much in the same way as Froebel proposed. The lack of teachers compelled Girard to adopt the monitorial system (1816), which, strangely enough, formed the center of attack on the part of his opponents. His school was divided into four grades, and each subject was reviewed anew and expanded in each grade. He won the affection of his pupils to a remarkable degree, and on his way to and from school he was always attended by a large group of them.

His chief work was the *Langue maternelle enseignée à la Jeunesse comme Moyen de Développement intellectuel, moral et religieux* (*The vernacular taught to the young as a means of intellectual, moral, and religious development*), in seven volumes, the first dealing with his pedagogical views. Here he recognizes the loosening of the bonds of family, church, and state, and for that reason urges control through moral and religious education. This work secured him in 1844 the prize awarded by the Paris Academy. Other works were *Dialogues sur l'Institution des Écoles de Campagne*, *Divers Discours et Dissertations sur des Sujets de Pédagogie générale*, *Des Moyens d'attacher la Jeunesse à ses Études et d'activer ses Progrès*.

#### GIRARD, STEPHEN (1750-1831)

— Founder of Girard College for Orphans, attended the schools of France, but was largely self-educated. He was for many years engaged in commercial pursuits, and left his fortune to various philanthropic and educational institutions. He bequeathed \$2,000,000 for the establishment of a college for orphans in Philadelphia. W. S. M.

**GIRLS, EDUCATION OF** — The various aspects of this subject are treated under separate titles. The existing practices concerning the education of girls with boys are presented under the title COEDUCATION. One phase of this question is discussed briefly under SEGREGATION. The history of the education of girls in America is included in the article on COLONIAL PERIOD IN AMERICAN EDUCATION. The early history of European practice is included in the article on MIDDLE AGES, EDUCATION IN. The general place of girls' education in various countries at the present time is given in the articles on the separate national systems. The entire subject of higher education is treated *in extenso* under the caption WOMEN, HIGHER EDUCATION OF.

#### GIRLS' PUBLIC DAY SCHOOL TRUST.

— An organization founded in England in 1872 to provide secondary education for girls. It was an outcome of the larger movement which centered in the National Union for Improving the Education of Women. The Trust numbered among its promoters Mrs William Grey, Miss Gurney, and Sir J. P. Kay-Shuttleworth. The work was organized on a commercial basis, and the shareholders receive a dividend of five per cent, any surplus being devoted to improving the schools. The first school was opened at Chelsea. The aim of the Trust is declared to be to provide for girls opportunities similar to those open to boys in the great Public Schools. "Particular stress is laid on the formation of character by moral and religious training and for fitting girls for the practical business and duties of life." A full secondary school course is provided in all the schools, which number more than thirty and have over 7000 pupils. A training department for teachers in secondary schools, as well as in drawing and music, is maintained at the Clapham High School, which also prepares for the Teachers' Diploma of London and Cambridge Universities and the Froebel Certificate. Special courses in domestic economy are given in some schools to pupils who have completed the regular courses. The fees charged vary according to the age of the pupil from £9 9s. to £15 15s. (\$47-\$78 a year). A few scholarships are maintained at each school.

**GIRTON COLLEGE, CAMBRIDGE, ENGLAND** — An institution founded in 1869 at

Benslow House, Hitchin, for the higher education of women. It was the outcome of the efforts of Miss Emily Davies who had unsuccessfully tried to influence the Schools Inquiry Commission (1865-1867) to support the establishment of such an institution. Through her book *The Higher Education of Women* (1866) she had contributed to the progress of the women's educational movement in England. In 1868 she secured influential support and subscriptions which led to the opening of the house at Hitchin with six students. In 1873 the college was moved to Girton College, near Cambridge. Instruction was given by the resident tutors and several professors of the University along the lines of the university requirements, and the students were admitted to university lectures by courtesy. In 1881 the Senate granted permission to the students to present themselves for the university Tripos examinations for degrees, the College grants degree certificates, but not degrees on the results. At the same time the lectures were thrown open to the women. The remarkable successes of the students gave a considerable impetus to the cause of higher education of women, a large majority of the alumnae having devoted themselves to teaching in girls' secondary schools. The enrollment of the college in 1909-1910 was 158.

DAVIES, EMILY *Questions relating to Women, 1860-1908* (Cambridge, 1910).

**GLADSTONE, WILLIAM EWART** (1809-1898) — The great English statesman did not play as great a part in the development of English education as might be expected from his general interest in national welfare and progress. He approached the question of elementary education almost entirely with a strong belief in the claims of an established church. In 1838 he was a member of the Select Committee for the Education of the Poorer Classes appointed to consider the best means of providing useful education in large towns. Gladstone insisted on religious education as a basis for state aid. It was about this time, too, that he proposed the establishment of teachers' training schools in every diocese, and the licensing of teachers by bishops. In 1854 he was instrumental in removing tests on admission and graduation at Oxford, although he insisted that the teaching and governing remain functions of the Church of England. He was opposed to a Crown Commission to inquire into the universities and would have preferred reform from within. When the Education Bill of 1870 was brought forward by Forster (*qv*), Gladstone was lukewarm in his support. As he himself admitted later in a review of a biography of Forster (*Nineteenth Century*, September, 1888), his views "were by no means identical with the views of Forster."

"My responsibility," he writes, "is that of concurrence rather than of authorship." He would have preferred a system of local option on the question of religious instruction, for, as he says, "in all things, including education, I prefer voluntary to legal machinery, when the thing can be well done either way." In 1873 he undertook the difficult question of Irish University Reform, and in attempting to compromise met with the opposition of both Catholics and Protestants on account of his "gigantic scheme of godless education."

As a scholar Gladstone stood high. His love for the classics ranked almost next to his devotion to his religion. Any proposal to introduce pure science, natural science, modern languages, and modern history as subjects equivalent to Latin and Greek he refused to consider as possible, all of the new subjects he regarded as "auxiliary" to classical training. And his argument for classics was based not only on their cultural and disciplinary value but on the fact that "European civilization from the middle ages downwards is the compound of two great factors, the Christian religion for the spirit of man, and the Greek, and in a secondary degree the Roman, discipline for his mind and intellect." At the same time he recognized that such an education was for the élite only, "it can only apply in full to the small proportion of the youth of any country who are to become in the fullest sense educated." While Gladstone's influence on English education was very slight, the point of view of the leader demands attention, for it is representative of the opinions prevailing in England in the middle of the nineteenth century.

**GLASGOW, THE UNIVERSITY OF.**—A coeducational institution situated in Glasgow, Scotland, founded (1451), like most other ancient universities, by the authority of the Church of Rome. The Bishop of Glasgow and his successors in office were appointed to rule over the college. Up till 1460 the university seems to have had no permanent home, but in that year, James, Lord Hamilton, bequeathed to the Principal of the College of Arts, and his successors in office, a tenement with four acres of land adjoining, situated in the old High Street of the city. In buildings on this site, the classes of the university continued to meet for upwards of four hundred years, until the new university buildings situated at Gilmorehill were ready for occupation in 1870. Owing to the ecclesiastical changes, and the political conditions of the country, the university passed through many vicissitudes during the first two

hundred years after its establishment, and it was not until the beginning of the eighteenth century that it began to make steady, continuous, and permanent progress. This manifested itself in (1) the specialization of the teaching within the University, and (2) in the establishment of new chairs. During the last decade of the seventeenth century and the whole of the eighteenth century, eight new professorships were established, viz. mathematics (1691), humanity (1706), oriental languages (1709), civil law (1712), medicine (1712), history (1716), anatomy (1718), and astronomy (1760). Thereafter, for nearly fifty years, no additional chairs were added, but beginning with the establishment of the chair of natural history (1807) there came the establishment of professorships in surgery (1815), midwifery (1815), chemistry (1817), botany (1818), materia medica (1831), institutes of medicine (1839), forensic medicine (1839), civil engineering (1840), conveyancing (1861), English language and literature (1861), biblical criticism (1861), clinical surgery (1874), clinical medicine (1874), naval architecture (1883), history (1893), pathology (1893), and political economy (1896). During the present century separate chairs have been founded in geology (1903), zoology (1903), and mining (1906). Further, since 1892 many additional lectureships have also been established, the more important being those of French, German, Italian, and Celtic in the Department of Language and Literature, education, psychology, and political philosophy in the Department of Philosophy, constitutional law and history, and economic history in the Department of History and Law. In addition, both in medicine and in science, lectureships in the more specialized departments of these subjects have been recently instituted.

The present buildings in the west of the city were opened in 1870. In addition to the buildings used for teaching, there is also the Bute Hall, the gift of the late Marquis of Bute. Here are held the graduation and other important ceremonies of the university. Residences are provided within the grounds for the principal and several of the professors. In 1893, as a result of the admission of women students to the universities of Scotland, the Governors of Queen Margaret College, an institution for the higher education of women and housed in North Park, handed over to the university its buildings and grounds for the use of the women students. Since then Queen Margaret College has ceased to be an independent institution and has been wholly incorporated with the university. Within recent years, extensive additions have been made to the original buildings at Gilmorehill, including (a) classrooms and laboratories for the teaching of engineering; (b) lecture rooms, a museum and herbarium for the teaching of botany, and (c) an extension of the anatomical depart-

ment Two other groups of buildings have lately been added, one for the teaching of physics, the other to provide better accommodation and equipment for the teaching of physiology, materia medica, and forensic medicine.

The present constitution of the university dates from the passing of the Universities (Scotland) Act of 1858, and as amended by the Act of 1889, and is similar to that of Edinburgh (*qv*) and other Scottish universities. The University Court, now composed of fourteen members, representative of the General Council of graduates of the *Senatus Academicus* and of the students, is the chief governing and administrative body; the duties of the *Senatus* being mainly concerned with the regulation and superintendence of the teaching and discipline within the university. The work of the university is, at present, divided into five faculties or departments, viz: the faculties of (1) arts, (2) science, (3) medicine, (4) law, and (5) divinity.

The Faculty of Arts is the largest in the university and is attended by more than 1200 students yearly. It provides a course for graduation in arts. The work of the faculty is divided into four departments, viz: those of language and literature, of mental philosophy, of mathematics and science, and of history and law. The course for graduation may be taken either in five or six subjects, provided that when a course of five subjects is taken, two of these must be studied during two sessions, and an examination passed on a higher standard than in the other three subjects of the course. If a curriculum of six subjects is chosen, one of these must be studied during two years, and of the other five, two must be cognate (*e.g.* logic and moral philosophy) and must be taken up in separate sessions. A further regulation enacts that every curriculum for the ordinary degree in arts must include a philosophical subject, either logic or moral philosophy. The degree with honors in arts may be taken in the following departments of study, viz: (a) classics, (b) philosophy, (c) mathematics and natural philosophy, (d) English, (e) history, (f) economics, (g) French and German, (h) French, Italian, Latin (any two), (i) Germanic language and literature (with English), (j) Celtic language and literature (with Latin), (k) Semitic languages (Hebrew and Arabic).

In the Faculty of Science, in addition to the course leading to the degree of Bachelor in Pure Science, courses are also provided in applied science, leading to the bachelor's degree in (a) engineering, in (b) agriculture, in (c) public health, and in (d) pharmacy. Higher degrees in both science and arts may be conferred on graduates on the presentation and approval of a thesis after five years from the date of their graduation.

In the Faculty of Medicine, courses are provided for students leading to the degree of

Bachelor of Medicine and Bachelor of Surgery (M B, C M). The course normally extends over five years. Holders of the lower degree may on certain conditions proceed thereafter to the degree of Doctor of Medicine (M D) or Master of Surgery (M Ch).

The Faculty of Law provides two degree courses, one open only to graduates and leading to the degree of Bachelor of Laws (LL B), and the other and lower degree of Bachelor of Law (B L) open to non-graduates in arts on certain conditions. The faculty of divinity provides a course for graduates in arts leading to the degree of Bachelor of Divinity (B D). Honorary degrees may also be conferred in law (LL D) and in divinity (D D).

The total number of students in attendance during session 1909-1910 was 2728, made up as follows: arts, 1253, medicine, 698, science, 443, law, 204, divinity, 61. Enrolled in more than one faculty 20, single-course students, 48. Since 1892, when the University was thrown open to women students, the number has gradually increased. In session 1909-1910 women students numbered 642, of whom 534 were enrolled in the Faculty of Arts and 71 in the Faculty of Medicine. The staff of the University, at present, embraces 32 professors and 52 lecturers (exclusive of assistants to professors). A D

**GLOMERY** — This word is simply a corruption of the word "grammar," dating (apparently) from the thirteenth century. Owing to its use at Cambridge as late as the sixteenth century, where the Master of Glomery (*Magister glomeræ*) in 1533-1544 exercised the functions, afterwards performed by the professor of Greek and the Public Orator, of presenting for degrees, a great deal of wild guessing took place as to its meaning. Fuller, in his *History of the University of Cambridge*, published in 1659, leaves it as a mystery. "Let it suffice us to know that the original of the word seems barbarous, his office narrow and topical (confined to Cambridge) and his certain use at this day antiquated and forgotten." Even Dr Rashdall, in his *Universities of Europe*, speaks of the Master of Glomery as a "wholly peculiar Cambridge institution." Dr Caius, the Elizabethan historian of Cambridge, had derived the name "as

if so called a *glomerando* from 'going round about' the Regent-houses to collect the votes at congregations, or from 'gathering their votesglomerated,' that is, rolled and rounded up in a piece of paper."

In point of fact the Master of Glomery at Cambridge was at first nothing more than the grammar schoolmaster. The first extant notice of him is in a document of the year 1276, in which the Bishop of Ely regulated the relations and defined the area of jurisdiction of the Master of Glomery, the Chancellor of the university, and the Archdeacon of Ely. The grammar master is to have exclusive jurisdiction in all cases in which grammar scholars (*glomerelli*) are dependents, as other masters have in the cases of their scholars, so that whether university scholars or laymen wish to convene grammar scholars or get anything from them by judicial process they shall do it before the Glomery Master unless it be a question of rent of lodgings or involving loss of university rights when the Chancellor is to decide. The grammar beadle was not to carry his mace in university convocations nor before the Chancellor, but he might continue to do so elsewhere, especially when executing his office. This document is of great interest in the history of universities as it showed how the later jurisdiction of the Chancellor of the students of the higher or university faculties had eclipsed the glory of the preexisting grammar schoolmaster. That the Glomery Master was nothing more is clear from the oath which he took on admission by the Archdeacon of Ely to discharge all the duties of the glomery school of Cambridge (*opera scholarum glomeriæ Cantabrigiæ*) without any extortion from the scholars. The oaths and names of the Glomery Masters until 1437 are preserved in the Archdeacon of Ely's book now at Caius College. The Glomery School was, under the title of Gramer Scole, granted to trustees of King's College and incorporated in its site in 1440, but the lane in which it had stood was still called Glomery Lane when Dr Caius wrote in the reign of Elizabeth. After 1437 the Glomery Master appeared to have been merely the superintendent of the grammar schools in Cambridge and head of the grammar faculty presenting candidates for the degree in grammar. The last who enjoyed the title was Sir John Cheke (*qv*) in 1533-1534, and it is presumed that his office was deemed to be merged in that of the Professor of Greek. That the term is not peculiar to Cambridge appears from the earliest account roll of the grammar school attached to Merton College, Oxford. In the year 1277, 20s was paid to the grammar master (*magistro glomerie*) for five boys for one term, or at the rate of 4s. a head. At Bury St Edmunds, in 1288 or 1289, an official issued a mandate against certain pedagogues wrongfully usurping the title of master who presumed to keep adulterine schools, pretending

to teach dialecticians, grammar scholars (*glomerellos*) against the will of the schoolmaster of St Edmunds, and directing their excommunication. A similar mandate, a few years later, was directed against John Harrison for teaching *glomerellos* and other pupils. At Salisbury in 1308 the grammar schoolhouse is described as *scole glomerie*, which in 1322 appears as *scole gramaticales*, thus establishing the identity of meaning beyond doubt.

The corruption is probably of French origin as it appears in the *Battle of the Seven Arts* of Henry d'Andely written about 1250 (ed A Heion, 1881) in which the glomerians assemble at Orleans, where classics were still the predominant study, under the banner of grammar, to attack the logicians intrenched at Paris.

**GNOSTICISM** — During the second century of the Christian Era there arose a strange medley of doctrinal speculations, known as Gnosticism, which disturbed the peace of the Church and necessitated the development of a Christian theology. They represented a systematic effort to fuse Christianity into the vast fabric of speculation erected by philosophic thought. Men of keen intelligence, having embraced Christianity, naturally applied to its investigation the methods of Jewish learning and Greek philosophy. There soon sprang into existence a multitude of pantheistic-idealistic sects, varying widely in their ideas, but agreeing upon certain basic principles. They all professed a *gnosis* or spiritual enlightenment. They regarded Christianity as a system of metaphysics to be expressed in the categories of speculative thought. They held that the soul attains its rightful end, not by faith and works, but by receiving a tradition of knowledge, communicated only to the initiated few and to which the masses of mankind could not attain. This doctrine of salvation by knowledge limited the enjoyment of religion to a few illuminati. The Gnostics were "those who knew," a superior order of beings apart from ordinary believers. Most of them were dualists. Adopting the familiar axiom of the philosophers, "evil inheres in matter," they despised the physical world as the creation, not of the Supreme Deity, but of a Demiurge, a limited secondary god. Some said matter was eternal, others explained it as rubbish remaining after the completion of the spiritual *pleroma*, the result of accident or negligence in the process of creation. They regarded the human body as an incumbrance in which the soul is held captive and from which it will escape at death. They denied the resurrection of the body and explained away the Incarnation of Christ, generally adopting the *docetic* theory, that Christ was a pure spirit with a phantasmal

or apparitional body. To account for the evolution of the universe, they called into existence a series of "endless genealogies," a long chain of lower gods or *æons*, connecting the world with God. The Demurge and the material world were more or less antagonistic to God, and this present existence was essentially evil. Thus Gnosticism was a philosophic and religious pessimism. It was too speculative to be bound by scriptures, creeds, and sacraments. There was no central authority. Every Gnostic teacher shaped his theories to suit himself and garnished them with "great swelling words." The Gnostics were more active than the orthodox Christians in literary and educational work. Their great teachers — Basilides (c 125), Valentinus (125–140), Bardesanes (154–222), Heraclion (c 160), and Marcion (c 150) made many disciples who became famous educators and founded colleges in Antioch, Alexandria, and other centers of learning to which multitudes of students were drawn. They produced a vast and varied collection of writings, most of which have perished. The Gnostic theories possess a curious interest for the scientist, and especially the psychologist, because of their original and often fantastic efforts to solve the great problems of life and mind. **GODDARD, WILLIAM STANLEY** (1757–1845) — One of the most influential Headmasters of Winchester College. Himself educated at Winchester and Merton College, Oxford, where he graduated B A in 1781, he became usher or second master at his old school in 1784. Under Dr Warton, headmaster at this time, the numbers had dwindled, discipline was lax, and scholarship was low. As a result of a "rebellion" of the pupils, Dr Warton resigned and was succeeded by Dr Goddard in 1796. He introduced a new spirit into the school; the numbers increased, the standard of scholarship was raised, but above all he showed great tact in managing boys, in putting trust in them, and in permitting a certain measure of self-government. Dr Arnold was a pupil at Winchester under Goddard, and there can be no doubt that he owed much to his influence and to Winchester traditions, to Goddard's tact. Dr. Arnold frequently recurred. A large number of boys educated at Winchester at this period attained eminence in later life. Dr Goddard retired in 1809, became prebendary of St Paul's in 1814, canon of

Salisbury in 1829, and died in 1845. He gave, during his lifetime, £25,000 to his old school to be used for masters' salaries in place of the iniquitous system of gratuities.

**GODWIN, MARY WOLLSTONECRAFT** (1759–1797) — An English author, the wife of William Godwin (*qv*), whose political and social theories she shared. Impatient with a system of female education which made puppets of girls and killed individuality, she wrote, in 1792, the *Vindication of the Rights of Women*, a remarkably capable plea for the political, social, and intellectual enfranchisement of women. Her general thesis is "make women rational creatures and free citizens and they will quickly become good wives and mothers; that is, if men do not neglect the duties of husbands and fathers." Women should be "free from all restraints by allowing them to participate in the inherent rights of mankind." Hence she was strongly opposed to the type of education proposed by Rousseau for Sophia. In a chapter on National Education, Miss Godwin takes occasion to criticize severely private education and private and boarding schools, which are marked by tyranny and slavery to forms. The private schools give little thought to moral training, the masters considering their duty done if they teach Latin and Greek and send a few good scholars to the universities. But "it is not for the benefit of society that a few brilliant men should be brought forward at the expense of the multitude." Hence she advocates a system of national education in the first years, at least, on a purely democratic basis. A national system should provide a common school for children of all classes from the age of five to nine. Reading, writing, and arithmetic, natural history, simple experiments in natural philosophy, botany, mechanics, astronomy, religion, history, and politics would make up the curriculum, but play in the open air must never be neglected. After the age of nine the poorer children would go to industrial schools for vocational training, while the rich would study languages, science, history, and politics. Both sexes were to be educated together, for coeducation serves to perfect both not only morally, but for companionship through life.

In her other work, *Thoughts on the Education of Daughters* (1787), she also attacks the narrow training of girls for the drawing room, which was so characteristic of the time. Suggestions are here offered for the education of girls which would replace the prevailing superficiality, weakness, dependence, and affectation of women by a healthy independence and desire

to share in the world's work as the companions of men. Mrs Godwin, always devoutly religious, took a strong interest in moral training of children, and translated Salzmann's *Moralisches Elementarbuch* (*Elements of Morality*, 1790), with modifications to suit English conditions (See SALZMANN, CHRISTIAN GOTTHILF)

**GODWIN, WILLIAM** (1756-1836) — English political philosopher, novelist, and anti-quarian, the son of a dissenting minister and himself a minister from 1778 to 1783, when he came under the influence of the French philosophers and English republicans. He sympathized with the theory of the French Revolution, but hardly with the methods of procedure. He associated with the most prominent English radicals, and in 1793 his *Enquiry concerning Political Justice and its Influence on Morals and Happiness* placed him at the head of the extremists. This work, which attracted considerable attention and was a source of inspiration to many young men, was an attack on all forms of government as means of constraint and control. The relations of individuals in society should be regulated on a basis of justice, "a principle which proposes to itself the production of the greatest sum of pleasure and happiness," and this principle in turn depends on reason. Godwin's belief in the perfectability of man was connected with his belief that reason could be improved indefinitely. Hence he believed in the boundless possibilities of education, of which all alike were capable. In this work Godwin held that the differences between individuals due to heredity were of small account and would disappear under the influence of a common education. The administration of education he would not leave in the control of a national government, since it would tend to perpetuate its own opinions and would prevent the development of an open mind ready to search for truth rather than to accept opinions, and, further, private endeavor on the part of teacher and taught would be accompanied by "enthusiasm and energy." But while this work was evidently written under French influence, there is little trace of Rousseau in Godwin's educational writings. *The Enquirer, Reflections on Education, Manners, and Literature* (London, 1797), and *Thoughts on Man; his Nature, Production, and Dis-*

*coveries* (London, 1831). In the Preface of the earlier work the author declares his belief in the intimate connection between the cause of political reform and the cause of intellectual and literary refinement. The objects of education are the attainment of happiness, virtue, and wisdom, each of these depending on the other. In discussing the value of private (tutorial) or public education (*i.e.* in school) Godwin argues in favor of the latter on social grounds, for "to practice upon a smaller theater the business of the world must be one of the most desirable sources of instruction and morals," and further, the child learns more from intercourse with his companions than from the teacher. The purpose of education is to "provide against the age of five and twenty a mind well regulated, active, and prepared to learn." Hence the importance which he attaches to habit formation in the young; the school is not to impart knowledge so much as habits of intellectual activity. Godwin accepted the disciplinary value of the classics, for the retention of which he states arguments which have not since been improved upon by their advocates. But the most remarkable pronouncement is that on method in the essay *Of the Communication of Knowledge*, an anticipation of the doctrine of interest. "The best motive to learn is a perception of the value of the thing learned, the worst motive . . . may well be affirmed to be constraint and fear, there is a motive between these . . . desire not springing from the intrinsic excellence of the object, but from the accidental attractions which the teacher may have attached to it." If his plan of giving the pupil a motive to learn and smoothing out his difficulties is adopted, the author believes that the face of education will be changed and "no such characters are left upon the scene as either preceptor or pupil." According to the new method "the pupil should go first and the master follow." While he admires "the treatise of Rousseau upon education" as "probably a work of the highest value," he criticizes his system severely because of lack of frankness on the part of the tutor and because of the deception played on the pupil, for "his whole system is a series of tricks, a puppet-show exhibition, of which the master holds the wires, and the scholar is never to suspect in what manner they are moved."

In the *Thoughts* Godwin has clearly made some advance in educational theory. While he still has faith in the great educational value of the classics, he advises that a pupil who has no ability for language should be taken away from those studies. More respect should be shown to individuality; the capacities of a scholar should be studied and his career and education should follow accordingly. An ill-adapted curriculum is frequently at fault rather than innate stupidity, for "nature never made a dunce." Godwin is thus compelled to recommend a wider curriculum, including

"the rudiments of all the sciences that are in ordinary use," than he had done in the *Enquirer*. In this volume there is also an attack on phrenology and insistence on the unity of the mind. The author discredits the view put forward by the phrenologists that an individual is endowed with special abilities, and shows that a child may be born with general ability which can be directed to special ends. Godwin's political work was soon forgotten, and his educational writings, though full of sound common-sense views and sympathy, did not exercise any marked influence.

**GOETHE, JOHANN WOLFGANG** (1749-1832) — Although Goethe has not formulated any connected system of education, his works contain some of the deepest and most fruitful pedagogic thoughts. His interest in education was early aroused through the works of Basedow and Rousseau, in Weimar he directed the education of the son of Frau von Stem, a young man of rather mediocre talents, whom Schiller, however, pronounced a "pedagogic masterpiece", and, as a minister, he exerted a great influence on the educational affairs of the duchy of Weimar. Above all, Goethe studied the development of his own mind, striving to raise himself to higher and higher levels. This conscious process of self-education, coupled with the poet's profound insight into human life, invests Goethe's ideas on education with a great interest and significance. Goethe realizes the necessity of education, although he believes that the educator cannot put anything into the mind which is not already there by nature. The method of education must be self-activity, education must be positive and not repressive, education through fear is the worst of all.

The object of education, according to Goethe, is the development, from within, of all the powers of the human mind, so as to produce an harmonious personality which will be active in the service of society. This social view of education finds expression in the description of the "pedagogic province" of his novel *Wilhelm Meister's Wanderjahre*. In this province, which forms a small state in itself, and from which all unpedagogic influences are carefully excluded, boys are educated in common, each for that kind of occupation for which he seems to show the greatest aptitude. Their education is thoroughly practical, and is permeated by an ethical spirit to which Goethe gives the name of "reverence". Three kinds of reverence are inculcated: for that which is above us, that which is around us, and that

which is beneath us, in other words, for God, Humanity, and Nature. From these three reverences springs the highest, which is self-reverence. These ethical teachings are embodied in appropriate symbols and transmitted by song. **F. M.**

**GOLDEN SECTION.** — When a spacial figure is so divided that it obeys the formula — the longest side is to the shortest side as the sum of the two sides is to the longest side, the division is especially pleasing to the observer and is designated the golden section. This formula is obeyed by ornamental crosses, by books and pictures, to such an extent that it is evident that the relation is common and natural to even untrained individuals. The explanation of the satisfactory character of this division is not easy to give. Such a division departs from absolute symmetry enough to give variety, and it is near enough to symmetry so that neither dimension is extravagantly different from the other. **C. H. J.**

- FECHNER, G. T. *Zur experimentalen Aesthetik* (Leipzig, 1871)

**GOLDSMITH, OLIVER** (1728-1774) — The English poet and writer has left among his writings some excellent descriptions of the life of an assistant or usher and a criticism of the education of his day. As a boy he had been moved about from school to school with but little intellectual profit from any of them. It is supposed that it is the master of the second school which he attended, Thomas Byrne, a retired soldier, who is the prototype of the Village Schoolmaster in the *Deserted Village*: —

"And still they gazed and still the wonder grew  
That one small head could carry all he knew"

As a student he was at Trinity College, Dublin, at Edinburgh, and at Louvain. For a time he assisted in a school kept by his brother, served as private tutor in Ireland, and was usher at Peckham Academy, so that his account of the humiliating position of the usher is based possibly on first-hand experience. It is in the same essay that he criticizes the declamatory style of educational writings and asks for a more scientific manner of presentation and for "didactic simplicity". Goldsmith attacks the numerous private boarding schools of the period. "Is any man unfit for any of the professions,

he finds his last resource in setting up school," with no small profit to himself. The state should interfere and at least "cast its eye to their instructors," a suggestion which still remains to be put into effect in England. Better salaries are required to secure abler men for the teaching profession. The public schools are superior to private schools, for "it is not from their masters, but from their equals youth learn a knowledge of the world." Temperance and frugality, qualities which Goldsmith had negatively discovered to be desirable, should be taught in school, and moral tales should be introduced. Goldsmith further attacks the teaching of rhetoric and elocution, where conviction and a knowledge of the subject and language are of greater value. He was also opposed to the encyclopedic curriculum of his day, by which "the child soon becomes a talker in all and a master in none." Clearly something of "soft pedagogy" was already creeping into the schools, for Goldsmith mentions the futility of teaching language through textbooks with text on one side and literal translation on the other. Further, he says, "attempting to deceive children into instruction is only deceiving ourselves, and I know no passion capable of conquering a child's natural laziness but fear." In another work (*Present State of Polite Learning*) the author discusses the relative merits of travel and study in college, and decides in favor of the latter for the young man. The universities he divides into three groups: those which retain the scholastic tradition, — Prague, Louvain, and Padua, those which do not prescribe the length of residence for a degree nor control the students, — Edinburgh, Gottingen, Leyden, Geneva, and those which have a prescribed period of study and some control, — Oxford, Cambridge, and Dublin. Dealing with the general characteristics of the universities he controverts the belief that they are places to advance learning, for "new improvements in learning are seldom adopted in colleges until admitted everywhere else. And this is right, we should always be cautious of teaching the rising generation uncertainties for truth." And lastly this modern touch may be added, "Learning is most advanced in populous cities, where chance often conspires with industry to promote it."

**GOLIARDS** — The name of a class of wandering students of the middle ages. They were drawn from the clerical orders and consisted of those who had no cure or office. The term is derived, according to Wright, from *gula*, and refers to their gluttonous and intemperate habits. They wandered from university to university as hangers-on of the higher clergy, or from one court to another, and led a riotous existence, living generally from hand to mouth. The bond which bound those who adopted this form of life together into a sort of fraternity was adherence to a mythical patron, Gohas or Goliath the Bishop, referred to also as *primas* and *archipoeta*. In his name and in his honor were perpetrated all the vices and pleasures which were incidental to a tramp life. To him were dedicated all the songs and literature which originated with this class, and under his patronage were made all the attacks against ecclesiastical authority and everything that was considered sacred, as, for example, the *Apocalypse Goliæ*, a parody on the Apocalypse of St John. The songs have been collected and published under the title of *Carmina Burana* (q v)

**GOODNOW, ISAAC T** (1814-1891) —

A pioneer of the common-school movement in Kansas, was educated at the Wesleyan academy at Wilbraham, Mass., and was engaged in secondary school work first in Massachusetts, Maine, and Rhode Island, and later in Kansas. He was president of Bluemont College from 1856 to 1863 and state superintendent of Kansas from 1863 to 1867  
 W. S. M.

**GOODRICH, CHAUNCEY ALLEN** (1790-1860) — Lexicographer; graduated from Yale College in 1810. He was tutor at Yale from 1812 to 1814 and professor from 1817 to 1839.

He was the author of several Greek and Latin textbooks, edited the *Quarterly Spectator*, and brought out numerous revised editions of the dictionary of his father-in-law, Noah Webster (*q.v.*).  
W. S. M.

**GOODRICH, SAMUEL GRISWOLD** (1793–1860) — Author of the Peter Parley books, published eighty-four textbooks and reading books for children. His textbooks include, besides readers and primers, histories, geographies, spelling books, and science books.  
W. S. M.

**GORDON, ROBERT** (1668–1731) — Founder of Robert Gordon's College, an institution for the education of boys in Aberdeen, Scotland; was born in 1668 and died in 1731. For many years he carried on business as a merchant in Dantzic and amassed considerable wealth. On his death, he left his fortune in trust to the magistrates and ministers of Aberdeen for "the building of an Hospital and for the maintenance and education of boys whose parents are poor and indigent and not able to maintain them at school, and to put them to trades and employments." The erection of the Hospital buildings was begun soon after the testator's death, but it was not until 1750 that the school was formally opened with fourteen boys, under the mastership of a Robert Abercrombie, minister at Fortde. From its foundation down to 1881, the institution was conducted on the basis of the original foundation as a hospital or boarding school for the sons of indigent burgesses. In the latter year, acting under powers conferred by the Endowed Institutions (Scotland Act), it was agreed to convert the Hospital School into a college or day school in which the chief subjects of instruction should be the English language and literature, history and geography, modern languages, mathematics, and the elements of physical and natural science. Provision was also made for the establishment of evening classes for youths and adults. The institution was hereafter designated as "Robert Gordon's College in Aberdeen." Quite recently, in 1910, the Constitution of the College has again been changed, and, in the future, Robert Gordon's College will become an integral part of the Aberdeen and North of Scotland Technical College, an institution designed to provide higher technical education for the North of Scotland, similar to that provided in the Glasgow and West of Scotland Technical College and in the Edinburgh Heriot-Watt Technical College.

**GORHAM, JOHN** (1793–1829) — Author of textbooks in chemistry and physics; was educated at Harvard College and the University of Edinburgh and was professor at Harvard.  
W. S. M.

**GOTHA, SCHOOL REFORM IN** — The small state of Saxe-Gotha, situated almost in the center of Germany, holds a position in the history of education which is almost unique. The earliest record of a school in the duchy is in 1299 when reference is made to a school in connection with the church in the town of Gotha. In 1327 two schools are mentioned, and a few years later a school of girls is referred to. Considerable activity was shown during the period of the Reformation. Myconius, a friend of Luther, became pastor and superintendent in Gotha in 1524. Influenced by Luther's *Letters to Councilors* and the *Letters to Pastors*, Myconius attempted to introduce some form of elementary education. The elements of a system are found in the instruction in reading which the pastors and sextons were ordered to give on Sundays. This lasted until the Thirty Years' War, when the small duchy was reduced to poverty and chaos like so many of her neighbors. But from this state of depression Gotha was raised through the efforts of a ruler whose interest in the welfare and education of his people placed him in the forefront. With a firm belief in education imbibed from his mother, Dorothea Maria, pupil and patron of Ratke (*q.v.*), Duke Ernest the Pious recognized that this was the only means for the regeneration of his country. Already in 1640 he ordered a school and church visitation to gather information as a basis for further action. He himself made some visits personally. For the reform of schools and the establishment of a system of education he summoned to his aid Andreas Reyher (*q.v.*) who had been a member of the philosophical faculty at Leipzig, rector of a gymnasium, and author of several school texts. Reyher was appointed rector of the gymnasium at Gotha in 1640. He was abreast of the best educational thought of his day, and was acquainted with the work of Alsted, Ratke, and Comenius (*q.v.*). The Duke commissioned him to draw up a *Methodus docendi* primarily for lower forms of the gymnasium, but useful also for other schools of the state. The result was the *Schulmethodus* (*School Method or Special and particular report, stating how, under the*

protection of the Lord, the boys and girls of villages, and the children belonging to the lower class of the population of towns, of this principality of Gotha can and shall be plainly and successfully taught. Written by the order of his Grace the Prince and printed in Gotha by Peter Schmieden in the year 1642) This work, which was carefully revised by the Duke, appeared in 1642 and again in 1648, 1658, 1662, and 1672 Attendance at school was made compulsory on pain of a fine not only for absence but for tardiness The teachers were ordered to be humane, and to avoid abuse and severity A fully prescribed time-table was issued The chief stress was laid on religious instruction, and the teachers were to avoid mere memory drill Writing, spelling, reading, and arithmetic became regular subjects for the elementary school The most remarkable addition was the study of natural and other useful sciences, including mensuration and surveying for boys, natural phenomena, geography, zoology, information was to be given on all natural objects in the neighborhood "Everything that can be shown to children should be shown" The oldest children were to be taught civics, something about the government of the state and the importance of education. An annual examination was to be held at which the superintendent was to examine the records of the previous year and compare with the progress made at the time of the examination

Twenty model schools were established, new inspectors were appointed, better teachers were secured, textbooks were written and distributed gratis to school children Among the textbooks which were written by Reyher may be mentioned the *Deutsch ABC- und Syllabenbuchlein für die Kinder im Fürstenthumb Gotha* (The German Hornbook and Speller for Children in the Principality of Gotha) 1641, *Teutsche Lesebuchlein* (German Reader) 1642; *Arithmetica*, and in 1656 the *Kurtzer Unterricht* (Short Instruction in natural objects, in some useful sciences, in ecclesiastical and secular institutions of the country and in some domestic rescripts) For the training of children in manners a *Short instruction on the behavior of children* was published in 1654 on conduct of children on rising, dressing, at meals, at school and church, at play, and among strangers The teachers were advised to study by themselves or with pastors and inspectors Their salaries were raised, a sick fund was established, and some provision was made for the maintenance of teachers' widows and orphans Although he realized the importance of training teachers, Duke Ernest could only charge his successors with the duty, since his own means would not permit the establishment of a system in his own day

But reforms were not confined to the elementary schools alone Under Reyher the gymnasium at Gotha gained a great reputation, and pupils were drawn from the noble classes from all parts of Europe The number of

classes was increased, and special attention was paid to the preparation of the older scholars for the university. The Duke frequently visited the school and took a special interest in the conduct of the pupils Many of these proceeded to Jena, but, while the influence of the Duke was limited in this university, he issued a regulation in 1657 for those of his own subjects who attended there, dealing with the aim of studies, the means to this end, and the distribution of time For the education of his own children, of whom he had eighteen, he drew up a rigorous regulation dealing with every hour of the day

But such a system could only last so long as he who inspired it lived The "Prince among educators and educator among Princes" died in 1675 and had already been preceded by his able assistant, Reyher, in 1673 From that date until the middle of the last century the educational history of Gotha is one of continued decline, due in some measure to the fact that the duchy was divided among the sons of Duke Ernest, and largely to the extravagance of the petty rulers who spent the country's wealth in cheap imitations of the Court of Versailles The decline was arrested for a brief period under Ernest the Wise (1772-1804), who, assisted by Haun, inaugurated a reform of the decayed schools of the state, teachers were trained, schools were inspected, harsh discipline was stopped, the appointment of old servants to schools was checked, better methods of teaching were introduced by the issue in 1801 by Haun of *The common school methodus or practical instruction for inspectors and teachers of every kind of elementary schools, also for private teachers, illustrated by correct tables constructed by J. E. Christian Haun* But the party of reaction again seized control on the death of Duke Ernest the Wise, and a real and lasting reform was not introduced until 1863, on the basis of which a system has been evolved which places the small duchy of Gotha among the leaders in the German educational system See ERNEST I, THE PIOUS; ERNEST II

## GÖTTINGEN, THE ROYAL GEORGE AUGUSTUS UNIVERSITY OF

— Founded by King George II of England, in his capacity as Elector of Hanover, the opening of the institution being celebrated with great ceremony in 1737, although instruction had actually begun three years prior to this date. The university forged to the front rapidly, and is to this day one of the most renowned of the German institutions of higher learning, having attracted a large number of English and American students, among the latter being Emerson, Longfellow, Baneroff, and Motley. Benjamin Franklin paid a visit to the university as early as 1766, and was made a member of the Royal Society of Science.

The university in its beginnings differed from those established during the second half of the sixteenth and during the seventeenth century in that the theological (Protestant) faculty was not emphasized to the detriment of the others, the healthy early development of the institution being attributable in large measure to the excellent administration of the Hanoverian minister, Von Munchhausen (until 1771). During the years of storm and stress at the beginning of the nineteenth century, Göttingen was included for six years in the Kingdom of Westphalia, but after the War of Liberation it was reunited to Hanover, which had been raised to the rank of a kingdom. A new era of prosperity was now ushered in, which unfortunately received a severe setback as a result of the dismissal in 1837 of seven of the most celebrated teachers of the university who had opposed the government in the constitutional conflict, the number including Jakob and Wilhelm Grimm and the historians Dahlmann and Gervinus. In 1866 Göttingen became a Prussian institution, but its loss of independence—it had been the sole Hanoverian university—was by no means accompanied by a decline in efficiency, as the Prussian Ministry has always evinced a warm interest in the institution, which has been manifested in recent years by the erection of a number of splendid medical institutes.

The faculty of philosophy is by far the largest branch of the university, and includes the oldest philological seminar in Germany, as well as a picture gallery and a collection of engravings as adjuncts of the work in the history of art. The anatomical institute contains Blumenbach's famous collection of skulls. Considerable emphasis has been and is still laid at Göttingen upon the subject of mathe-

## GOUCHER COLLEGE

matics, while the departments of physics and physical chemistry are also widely known. The university library, an important collection from the very first, contains over 550,000 volumes and almost 7000 manuscripts, it being the largest university library in Germany. The university also contains a riding academy and a swimming pool. A German institute for foreign students, the Bottinger Studienhaus, established by an Elberfeld merchant in 1909, was transferred to the university of Berlin (1911). The annual budget of the university amounts to about \$400,000. The town is also the headquarters of a famous Royal Society of Science (*Gesellschaft der Wissenschaften*—1751, 1893), and contains a professional school for *Feinmechanik*.

In addition to the scholars referred to above, mention may be made of Albrecht von Haller in science, Heyne in philology, Wilhelm Weber in physics, Wohler in chemistry, Gauss in mathematics, Curtius, Wartz, and Roscher in history, Jhering and Planck in jurisprudence, and more recently Moritz Heyne in Germanic philology. Heinrich Heine was a student at Göttingen from 1820 to 1821, Bismarck from 1832 to 1833.

During the winter semester of 1909-1910 Göttingen ranked seventh in point of attendance among the German universities, enrolling 2342 students (217 women), of whom 112 (57 women) were auditors. As at a number of other German universities, there are more students (1419) enrolled in the faculty of philosophy than in all of the others combined, including the great majority of matriculated women. The law faculty, which enjoys a high reputation, also has a large attendance (432), the school of medicine attracting 262 students and that of theology 117. In the winter semester of 1910 there were 2233 students in attendance.

## GOUCHER COLLEGE, BALTIMORE, MD.

— An institution for the higher education of women, founded in 1884 by the Baltimore Conference of the Methodist Episcopal Church as the Woman's College of Baltimore. The college was opened in 1888. The present name was adopted in 1910. The entrance requirements are fifteen units of high school work, and the A B degree is conferred at the end of a four-years course, consisting of certain required and elective subjects, with a major in one department. In cooperation with Johns

## GOUGE

Hopkins University a College Course for Teachers is conducted by the faculties of both institutions, women students satisfying the requirements of these courses are admitted to the A. B. degree of Goucher College. The number of students enrolled in 1909-1910 was 367. There were thirty-three members on the instructing staff.

**GOUGE, THOMAS** (1609-1681) — Dissenting minister and philanthropist, educated at Eton and Cambridge. Until the Uniformity Act of 1662 he held a living in London, in which he conducted catechetical classes and employed the poor in spinning flax and hemp, a type of poor relief taken up on a wide scale by his friend Firmin (*qv*). Gouge's most important work, however, was the evangelization of Wales, which he undertook in 1672. He established schools, and employed teachers to give instruction in English and the catechism. Ultimately about three hundred schools were established. In addition he also distributed, mainly at his own expense, religious literature. In 1674 a trust for this purpose was established, including eminent churchmen and dissenters, and the Bible, Book of Common Prayer, Church Catechism, and other works were made accessible to the Welsh either through free distribution or at a very low price. So far as Gouge's schools are concerned, it would seem from Strype's evidence that they continued after his death until the Society for the Promotion of Christian Knowledge (*qv*) became active in Wales (1730). Gouge, probably through the influence of Firmin, a governor of the institution, also devoted himself to catechizing the scholars of Christ's Hospital.

**GOWNS** — See ACADEMIC COSTUME.

**GRACE** — A term which originally meant a dispensation granted by a university or some faculty in it from the "elaborate and complicated regulations" required from candidates for degrees. In the early period few candidates required "graces," but by the fifteenth century the "grace" was asked for as a regular practice. At Oxford it was granted by the Congregation of Regents. Conditions were frequently imposed on the granting of graces involving the performance of some action or a contribution for some purpose, charitable or otherwise. Later a grace came to mean any decree of a university which involved a dispensation from statutory requirements. The term is still used in this sense of decrees of the Senate at Cambridge. A further use of the word is with reference to the permission given by a college or hall for one of its members to take a degree.

**GRACELAND COLLEGE, LAMONI, IA** — A coeducational institution opened in 1895 under the auspices of the Reorganized Church of Jesus Christ of Latter Day Saints. Preparatory, collegiate, normal, commercial, music, and oratory departments are maintained. An industrial department is provided to enable students to defray part of their expenses. The entrance requirements are equivalent to twelve units of high school work. The degrees of A. B. and B. S. are conferred on completion of the requirements. There is a faculty of thirteen members.

**GRADATION, GRADES, GRADED SCHOOLS.** — See GRADING AND PROMOTION.

**GRADE GROUP PLAN** — See GRADING AND PROMOTION.

**GRADE MEETINGS** — Teachers in service are given instruction through teachers' meetings variously composed. When the basis of determining the attendance is the grade or grades taught by the teachers, the name "grade meeting" is applied. Thus, there are first grade meetings, third and fourth grade meetings, or grammar grade meetings. H S  
See SUPERVISION OF TEACHING; TEACHERS IN SERVICE, TRAINING OF.

**GRADING AND PROMOTION** — As school systems become organized, the necessity of teaching children in groups composed of those of substantially equal attainments produces the graded system or graded school. An ideal system of grades presupposes that all the children in a given group shall be about the same age and of equal capacity for school work. A system of grading or classification or grouping by classes begins with the entrance into school of a large number of children not yet trained in school subjects. Those who advance regularly through a course of study have their progress marked at certain intervals by promotion, which is essentially a stage when reclassification seems desirable. Naturally the course of study is the foundation of grading. This program of work and of standards to be reached indicates divisions appropriate to each year or other interval. The course of study may be so framed at any given stage as to be capable of mastery by a large or small proportion of the children. It may lay stress on formal elements of subjects in which special details may be placed at a premium, thus resulting in the failure of a considerable number of ungifted children.

At any stage the object of a system of grading is to produce groups or classes that are fairly homogeneous as regards attainments at the moment, and also capacity to make a certain rate of progress throughout the course of study as organized. Grading and promotion thus come to be focusing points of a variety of problems growing out of the teaching of children in groups. Mechanization of school work first expresses itself in an inflexibility of grading and in a rigidity of promotion from one stage to another in the course of study.

The first fact to be noted is that the homogeneity of any group of children can be approximate only. Children of the same age not only differ among themselves as regards attainments in general, but also vary largely according to the particular type of attainment considered, for example, of two children A may be inferior to B in arithmetic, but superior to B in music. Furthermore, children of substantially equal attainments at a given time may differ considerably as regards their rate of learning the subject matter. The rate commonly employed in practice is that which has been determined by experience as one suitable to a majority of normal children. Manifestly such a rate must fail to take account of individuals who differ considerably from the normal. In general, consideration of the individual pupil tends to produce criticism of the graded system, because in any such system it will be found that not only are numerous individuals quite unsuited to its requirements, but that every individual at some point loses in opportunities because of the system employed. On the other hand it must be recognized that a system of grading is a necessary

measure of economy wherever children must be dealt with in large numbers.

Starting with the assumption that some system of grading is necessary and that the end of a system of grading is to produce groups so homogeneous as to make the maximum progress of all the individuals composing the group possible, the various attempts to modify the effects of its too great mechanization may be discussed. If, from a large number of children, there be removed the comparatively small number of individuals who vary greatly from the normal, there is a system of grading and promotion supplemented by the existence of special classes (*qv*), into which might be put those who by reason of excessive age are ill adapted to given grades, or those who, having deficient sense organs or being weak mentally, are manifestly incapable of keeping pace with any group of normal children. This removes from the grades the strongly marked variant cases, and gives the teacher opportunity to devote her efforts to a class more nearly homogeneous. Similarly such pupils as may retard the work of a class through increasing the difficulties of discipline may be put into special disciplinary classes (*qv*).

Even among fairly normal children it is found that not all can make the same rate of progress. Where a pupil is so obviously unable to maintain progress in his grade, without being in any sense defective, he may be transferred to a grade lower than his own. (See DEMOTION.) A system of grading has been devised whereby groups shall proceed, as it were, along parallel lines. This is sometimes known as the Cambridge system, and may be so systematized that a given course of study shall be completed in respectively seven, eight, or nine years, so far as given individuals are concerned. Fully carried out, this system not only provides for pupils who are persistently unequal in their ability to make progress, but also for those who at one stage of their school career may proceed rapidly and at another slowly. In large schools it is possible to still further extend the principle involved in the Cambridge system. Under close oversight of principal and teacher, pupils may be formed into groups as nearly homogeneous as possible, and the rate of progress may then be determined without reference to any fixed program, but with reference solely to the capacity of the group. The system has been made so elastic that individuals may be frequently shifted from one group to the other, according as they manifest capacity to proceed more rapidly or to require more time. This is sometimes referred to as the group system, and provides the maximum degree of elasticity in this direction. In a few instances it has been carried so far as to allow for a measurable shifting of pupils from group to group according as different subjects are being taken, but this requires extremely close supervision, and is

possible only in a school of very large size. Such classification or grading pupils by subjects is an arrangement which is more possible in schools with the departmental system (*qv*) than in others. Not only is such a system an element in flexible grading, but in the later years it makes articulation with the high school possible.

Flexibility of grading is sometimes attained by varying the demands made upon pupils for amount of acquisition in any given grade. This takes several forms. The class may be carried over a given section of the course of study at such a rate as to allow the more capable pupils to meet all the requirements, but the less capable to require a review. The first group may then be promoted, or, more commonly, may take additional work in the ground covered, while those less capable are acquiring necessary proficiency in the essential subjects. A more extended form is found where two groups of pupils are carried along side by side, the one containing the more capable, the other the less, the latter being required to take only the minimum amount of work and to reach the minimum standard required for promotion, while the former takes an enriched course of study, not necessarily advancing them in the essential branches. Both divisions are expected to cover substantially the same ground in the subjects essential to promotion. A further modification of this plan rests on a differentiation of teaching. It is sometimes known as the Batavia plan (*qv*), involving two teachers in a room, the first of whom gives mainly class instruction, while the second coaches individuals who need additional assistance in order to make the required rate of progress. A plan which is very similar is the division of a class into two groups, each alternately receiving the attention of the teacher, so that while one group is studying, the other is reciting. (See ALTERNATING SYSTEM)

All these systems are yet more or less in the experimental stage, and some of them involve administrative difficulties which can be met only in exceptional situations. It is evident, however, that all of them constitute important attempts to produce a system, which, while utilizing the economies and efficiency that result from a training of children in homogeneous groups, shall nevertheless have due regard to the individual in respect to those points at which his interest demands some variation from the standards imposed upon the group.

It should be noted that a few educators believe that a radically different system of grouping children may eventually prove more satisfactory. Instead of a homogeneous group, the late Professor Jackman of Chicago University believed that a group heterogeneous so far as the years and attainments of individuals were concerned could yet be formed into an

organic unity which would result in the maximum opportunities for progress of the individuals composing it. From his point of view a system of training based largely on activities would find in a given group old and young children, some bright and some dull, but each carrying on learning activities in conjunction with others in such a way as to finally attain a maximum result. This system of classification would naturally require the elaboration of pedagogical theories which are yet very hypothetical.

The passage from one grade to another in a systematized course of study is commonly called promotion. The failure of a child to pass this stage gives the phenomenon of retardation (*qv*), which is by some assumed to be an index of the efficiency of the results of teaching. In the search for incentives among school children, promotion and non-promotion are often utilized as sources of motive. The fear of non-promotion among some children can be the most powerful incentive to exertion, while with others who are inclined to be mischievous it may serve as an excellent deterrent to insure good conduct. At certain stages in the educational career of youths where promotion means advancement into other types of schools or into other types of opportunity, the event becomes comparable in its importance to the ceremony of initiation in primitive life. The ability of the German boy to pass the imperial examination, which entitles him to exemption from compulsory military service and barrack life, becomes an important factor in the social standing of the youth and his family.

Tests for promotion from one grade to another become important features not only in the administration of schools, but in determining fundamental characteristics in the course of study itself. A highly mechanical system tends to introduce external examinations as a basis for promotion and graduation. A system in which the teachers must be stimulated by external aids makes free use of written examinations. These developments were best exemplified in the English practice during the period of the so-called "payment by results" plan and in American cities during the period from 1870 to 1895. Even slight consideration will show that a system of written examinations will test certain forms of learning only, and will quite fail to test others. Where written examinations prevail, subjects susceptible to this form of test will be at a premium. Present American practice, however, tends not only toward flexible grading, but toward flexibility in the conditions for promotion. The teacher's judgment of the pupil's ability to proceed enters as a factor, as do also formal records made of a term's work. (See EXAMINATIONS)

In secondary schools there is an increasing tendency to grade the pupil on his ability in an individual subject rather than in all subjects

## GRADING AND PROMOTION

taken together Promotion by subject then comes to be the rule, and graduation is possible when a definite number of units have been reached

The future development of grading and promotion will rest more largely than in the past on a study of the needs and possibilities of children. The study of retardation (*qv*) is serving to analyze the causes of the non-promotion of children. Some of these causes are found in the course of study itself, some in matters like illness and irregular attendance, over which the school may have little control, and some in a failure to reach the individual as far as possible by more scientific grading. It is possible that future developments will show that certain of the subjects recognized in a course of study are of such a nature that definite stages of attainment or power not only can, but must, be recognized as a basis of grouping, whereas other subjects have only a secondary bearing on the ability of the child to work in one group rather than in another. Thus differentiation may indeed rest, to a certain extent, on the social importance of the subjects. For example, arithmetic is a subject lending itself easily to a graduated statement, and is also sufficiently important to be imposed as a condition of promotion. Nature study, on the other hand, is not easily graded, and its importance may be such as to make it a matter of indifference whether the pupil has completed it or not when the question of promotion is being considered. In some school systems a deliberate differentiation is now being made between "essential" and "additional" subjects, the former only being considered in connection with questions of promotion.

The operation of a flexible system of grading as described above will be affected by conclusions yet to be reached as to the number of different groups of pupils which a teacher in a given room may handle to advantage. Practice in many places now assumes that a grade to a room is the desirable condition. It is not clear, however, but that a more effective mastery of the art of teaching might not enable a teacher to carry at least two different grades or groups along side by side, with the maximum advantage to all concerned. GRADING BY PROMOTION. — See GRADING AND PROMOTION

GRADING, FLEXIBLE — See GRADING AND PROMOTION

GRADING, HYGIENE OF — Modern investigations have revolutionized the problem of grading. With the older pedagogy it was a relatively simple thing to classify pupils merely according to their scholastic attainments. Now many other factors must be considered, — physiological age, psychological age, ability to work and to resist fatigue, general physical condition, mental type as regards imagery, attention, and the like. Hence to-day the problem of grading is quite as much an hygienic as a pedagogical one.

Roberts, the English anthropologist, was one of the first to put special emphasis on the need of considering physical development in allotting pupils to the different grades. He made out a table giving the statures and weights of boys at different ages and the amount of time that should be allotted for study and sleep and rest, and he maintained that age alone is not sufficient to determine a child's position in such a table, that "A child who is much below the mean height and weight of his age should be placed a year below, and one who is a good deal above the mean, especially if the weight be good, may be advanced a year above that which his actual age requires," and that the same principles should be considered in the grading of girls as in the grading of boys. Dr Brahn and others have maintained that children should be graded according to their ability to work and to resist fatigue. Recently a demand for more than this has arisen. The studies by Crampton and others have shown the hygienic necessity of considering physiological age in all questions of grading and the like. His study was based on investigations of high school students, and his general conclusion was that, "In future all our thought concerning the years nine to seventeen must be released from the idea of chronological age. Statistics for groups or individuals respecting weight, height, strength, scholarship, mental or physical endurance, medical or social conditions, that are not referred to physiological age are inconsequential and misleading."

Dr Crampton's investigations were based on actual physical examinations. Sometimes under present conditions this is not practicable, and in lieu of this Mr Foster maintains that height is a good index of physiological age, and the investigations by Quirsfeld support this view. Professor Rotch of Harvard strongly maintains that the appearance and ossification

of the epiphyses of the wrist and fingers are a trustworthy index of the general osseous development, and this in turn of general physiological development. Hence he takes X-ray photographs of these bones, and determines physiological age from them. He distinguishes chronological age, anatomical age, physiological age, and functional cerebral age, and maintains that the normal correspondence of all these ages should be the standard for grading children, and that any other method of grouping is impractical and illusive. There is at present no consensus in regard to what is the best method of determining physiological age. More studies of this problem are greatly needed.

Psychological age also must of course be considered. But though tests of psychological ability and maturity have been advocated, none altogether satisfactory have yet been devised. The most important practical attempts have been in the use of mental tests, particularly the Binet tests, for detecting cases of arrested mental development. While idiots are not likely to be found in the public schools, imbeciles and feeble-minded of the higher grade, the so-called morons, are not infrequently found. The importance of detecting such cases has been vividly shown by Dr. Goddard, and further investigations and the perfection of such tests is greatly needed.

The public school must provide for three main classes of pupils, — the normal child of good ability, including the supernormal, on the one hand, the defective children on the other, including those mentally and physically deficient, and between these two groups the large class of children who are more or less backward from various causes. All these cases will be found discussed under the separate titles as BACKWARD PUPILS; BLIND, EDUCATION OF THE, CRIPPLED CHILDREN, EDUCATION OF THE, DEAF, EDUCATION OF THE, DEAF-BLIND, EDUCATION OF THE, DEFECTIVES, SCHOOLS FOR, EXCEPTIONAL CHILDREN, NERVOUS CHILDREN, EDUCATION OF, OPEN-AIR SCHOOL, RETARDATION AND ELIMINATION OF PUPILS, SPEECH DEFECTS, EDUCATIONAL TREATMENT OF, SPECIAL CLASSES, SUPERNORMAL CHILDREN, TUBERCULOUS CHILDREN, EDUCATION OF, etc.

Many special plans have been adopted. The plan which has received the widest attention, and which in a general way illustrates the principle upon which there is now a consensus, is the system of grading that has been used for many years in the schools of Mannheim in Germany. The main features of it are as follows, there is the ordinary school course of eight years, and besides the course for defectives, *Hilfsschulen*, such as are found in many German cities, with a four years' course, and between the ordinary course and the *Hilfsschulen* a course of six years which covers the same ground as the ordinary school course,

but has to do less with details, has smaller classes, and specially equipped teachers. Transfer from the shorter course to the fuller course or the reverse is easy at the end of each year (See GERMANY, EDUCATION IN). There have been many criticisms of this Mannheim system; but some plan of this kind is obviously necessary, and such a system seems to come nearer than any other which has been tried to meeting the demands upon which there is a consensus. This will not, however, solve the deeper problems of grading. While, if the plan is carried out with the cooperation of a school physician, as Dr. Moses maintains is always necessary, physical conditions will be regarded in the grading, nevertheless much more than this is desirable and some plan of grading that shall be based upon classification according to physiological age and ability scientifically determined must be devised.

While there is at present no consensus in regard to the methods of determining such development, the announcement of the principle is an important contribution. Grading merely according to scholastic attainments and chronological age can no longer suffice. Even pedagogical efficiency demands more than this. From the point of view of hygiene it is imperative that both in the vertical and the horizontal grading regard should be had for the physical condition and the stage of development. Modern studies have shown that from a third to one half of the children in any school are likely to be physically defective or suffering from chronic disease. Serious results are likely to follow when the weak and defective are required to do what the strong ought to do. Some of the normal have much greater endurance than others, some of them belong to one mental type, others to different types, and besides all this there are great individual differences. If we are to make any pretense to scientific pedagogy, to say nothing of hygiene, we must consider these facts and have a thoroughly different plan of grading based upon physiological and psychological age as well as scholastic attainments.

### GRADUATION, AGE OF, FROM AMERICAN COLLEGES.

— The question of age of graduation from college has constituted an important factor in the discussion of many college problems of the present. It has been popularly supposed that the age of graduation from colleges had gradually risen from generation to generation, and that the typical college student of the present is more mature than in the past; consequently that the college course of the present together with its administration might and should be a very different thing from that of the past and that the relation of college course to secondary school on the one hand and to the professional school on the other should be determined altogether irrespective of past conditions. The further assumption was that such relationships were not so determined, and that existing problems (see Problems of the College, under COLLEGE, AMERICAN) were thus created.

The accurate investigations into the facts do not reveal grounds for this general assumption. On the contrary, while there is a certain conflict of tendencies in different institutions, the slight preponderance of the tendency is toward a decrease of age rather than an increase. The most extensive investigation made was that by Professor W S Thomas, in 1903, involving eleven institutions and more than 20,000 students, and covering substantially the entire nineteenth century. The actual results of this investigation shown by ten-year periods is given in the following table:—

MEDIAN AGES OF GRADUATION BY DECADES

	DARTMOUTH		MIDDLEBURY		BOWDOIN		UNIVERSITY OF VERMONT		ADELPHI	
	Age	No.	Age	No.	Age	No.	Age	No.	Age	No.

## GRADUATION

This table indicates that the median age for Dartmouth has fallen (three months in one hundred and thirty years); that for Middlebury has risen (two months in seventy years), for Bowdoin the median age has risen two years since 1810, but has been falling for the past sixty years. In only two of the eleven institutions, the University of Alabama and Syracuse University, has the median age remained unchanged. It is evident that, whether this slight change has been an increase or a decrease, it is chiefly a matter of the individual colleges.

An averaging of the median ages of the several colleges also shows that since 1850 there has been a gradual but slight decline in the age of graduation, amounting to two months in all. A study of the average ages of graduates instead of the median ages brings the same relative results, though the arithmetical average runs a few months higher throughout the entire period than does the median age. This is because the few students that are relatively much older than the average of the group, of whom every college has some, diverge much more from the median than do those below the median, and tend to bring up the average disproportionately. It is the gradual disappearance of this group of very mature students during the past half century that is tending to lower both median and average age of graduation.

Of greater importance than the average or median age of graduation is the distribution of the graduates by years. A comparison of the aggregate of all graduates of these eleven colleges for the decade at the middle of the century with the decade at the close shows that not only the average and the median have remained practically the same, but that the distribution of the students is becoming far less wide. This is indicated by the following diagram, which gives the distribution of all students graduating in these eleven institutions for the two decades under consideration.

## GRADUATION

While the median age of graduation remains practically the same, 22 + years, the greater number are concentrated in the twenty-first, twenty-second, and twenty-third years. A further change is indicated by this diagram, which seems to bear out the old contention that the age of graduation was rising. The mode, indicating the year in which the greatest number of students graduated, falls in the first diagram in the twenty-first year, in the second in the twenty-second.

The significant fact which is indicated by this as well as by other data is that the student body is being unified and standardized as to age, as it never has been before, and that the entire group of college students is coming to be a body of young men between the ages of eighteen and twenty-three or twenty-four. The graduating body is largely concentrated in the years twenty-one to twenty-four.

The following chart giving the distribution for these colleges for the two decades, half a century apart, indicates this very definitely.—

The gradual disappearance of the very mature student accounts in a large measure for this aspect of the change. While the median age has remained approximately the same, the number graduating before the twenty-third year has greatly increased. The following chart shows this distribution for the past fifty years for the entire group of colleges studied.

The percentage of the graduates under twenty-three has risen from 50 to 57 per cent, indicating again that the impression, so generally held,

that the age of graduation had increased was based on the extreme or isolated instances.

A more recent investigation by Professor George D. Strayer, based upon ninety-three selected colleges and covering the first decade of the present century, shows substantially the same conditions. The median ages of graduation for the middle 50 per cent of the colleges are included within the limits, 22 years and 6 months and 22 years and 9 months. For women the median age is 22 years and 8 months, the middle 50 per cent falling between the limits 22 years and 23 years and 3 months.

The investigations conducted each quinquennial period by the authorities of Harvard University into the age of the entering class support substantially the same results. The average age of the entering class was 18 years and 9 months in 1876, and from that time to 1900 gradually increased to 19 years and 4 months, since which time it has, with slight variations, gradually decreased.

In general we may say that the assumption that there has been a great advance in the average age of the college graduates was an error; that there are but few institutions where such an increase has occurred, that this is offset by a corresponding decrease in other institutions; and that the change either way for the larger part of the nineteenth century was very slight. What is occurring is the elimination of the very young students and the very mature, and the standardizing of the entire group.

As in the early part of the nineteenth century the curriculum itself had a fixed organization and the student body was much differentiated in age, the reverse comes to be true toward the close of the century: the curriculum loses its fixed character and becomes fluid, but the student body becomes standardized as to age and the college comes to take a very definite place in our system of education of four years in length following four years of high school or preparatory and eight years of elementary school work, and approximating the eighteen to twenty-two years of the student life.

**GRAFE, HEINRICH** (1802-1868). — A German teacher and educational writer, born in Buttstadt in Thuringia. After studying mathematics, philosophy, and theology in the University of Jena (1820-1823), he first became a clergyman, then the principal of the city school at Jena. In 1840 he was appointed professor of pedagogy in the University of Jena, a position which two years later he changed for the principalship of a Realschule in Cassel. He took part in the political struggles of the year 1848, which caused his imprisonment, and afterwards forced him to flee to Switzerland. From there he was called as a principal to Bremen in 1855, and remained there until his death. His chief works are: *Allgemeine Pädagogik* (*General Pedagogy*, Leipzig, 1845), and *Die deutsche Volksschule* (*The German Public School*, Leipzig, 1847). F. M.

**GRAMMAR, ENGLISH — Historical Development** — The first work on this subject was actually written in Latin, viz the *Grammatica Anglicana* by P. G., who is supposed to be a certain P. Greenwood, in 1594. It is a booklet, containing short chapters on letters, syllables, parts of speech. The book professes to deal especially with those points in which English differs from Latin grammar. It is of interest because it contains a vocabulary of Chaucerian words, together with their signification. There is also the first treatment of the parsing, or, as it is called, "analysis" of English. In 1624 John Hewes published *A Perfect Survey of the English Tongue*. He claims that his book serves for the exposition of Lily's Latin Grammar rules. The author endeavors to deal with English expressions, *a posteriori*, as the groundwork for the Latin. Hewes thus treats of moods, tenses, cases as found in English, and thus leads on to the Latin. Hewes was succeeded by William Walker (1623-1682), who follows the same method, but develops it more fully in his famous *Treatise of English Particles* (published before 1660). Walker expounds English particles as the preliminary to learning to write Latin composition. In 1633 Charles Butler wrote the *English Grammar*, a work which gives a real English accidence independent of Latin. It goes into questions of spelling and gathers from Sir John Prince the story of four good secretaries writing in English from dictation, making many differences of spelling, whereas four noblemen writing the same in their language all wrote exactly the same letters. Butler traces the uncertainty in English spelling to the imperfection of the alphabet. Both Butler and Gill utilize the Anglo-Saxon signs for the different sounds of *th*. In 1640 Simon Daines published a book, exactly described by the title: *Orthoepeia Anglicana, or the first principall part of the English Grammar Teaching the Art of right speaking and pronouncing English, with certaine exact rules of Orthography, and rules of spelking or combining of syllables*,

and directions for keeping of stops or points between sentence and sentence. A work in itself absolute, and never known to be accomplished by any before. No lesse profitable than necessary for all sorts, as well Native as Foreigners, that desire to attaine the perfection of our English Tongue. Methodically composed by the industry and observation of Simon Daines, School-master of Hinthlesham in Suffes Lond 1640. The next English grammar was that "made" by Ben Jonson, the dramatist, "for the benefit of all strangers out of his observation of the English language how spoken and in use."

The grammar unfinished and not published until 1640, three years after Jonson's death, is accompanied with a Latin commentary. Jonson quotes first the older writers, e.g. Chaucer, Gower, Lydgate, Foxe, More, Ascham, Cheke, Jewel, so as to illustrate and authorize particular usages of grammar, and supplies items of historical treatment of syntax. In 1653 was published *A New English Grammar* by J. Wharton. This was professedly useful for scholars before entrance on the Latin tongue, and therefore starts a new period in the teaching of English. It was also devised, like Jonson's, for the use of strangers learning English. Wharton points out that English is "happy beyond both Latin and Greek," in that it "needeth little or no grammar at all." In the years 1711 and 1712 no less than three English grammars were published, viz that of John Brightland (*qv*) and Michael Marttaire (*qv*) and that of James Greenwood (*Essay towards a Practical English Grammar*). These grammars provoked an attack by the anonymous writers of *Bellum Grammaticale*, consisting of reflections on the three English grammars "published in about a year last past" in 1712. In 1762 Robert Lowth, Bishop of London, published *A Short Introduction to English Grammar*, which strongly emphasizes the question of good use in grammar. This was a work of considerable merit, ran through many editions in England, and was republished at Cambridge, Mass., in 1811. Lowth's work was criticized by William Cobbett in his well-known *Grammar of the English Language* in a series of letters, 1818. Cobbett states that his *Grammar* was intended for the use of schools and of young persons, "but more especially for the use of soldiers, sailors, apprentices and plough-boys." But still more popular than Cobbett's book was the *English Grammar* of Lindley Murray (*qv*), published in England in 1795. Both in England and America this was for many years the chief, almost only, English grammar used, particularly in girls' schools, for which it was first written. It went through some fifty editions, and an abridgment, first published in 1818, reached over 120 editions of ten thousand each. (See *Dictionary of National Biography*.) The first writer of an Anglo-Saxon grammar was Elizabeth Elstob (*qv*), 1715. The pioneer in the school teaching of historical English grammar

in England was Dr. Richard Morris, Headmaster from 1875 to 1888 of the Royal Masonic Institution for Boys at Wood Green near London. In 1872 he wrote his *Historical Outlines of English Accidence*, which went through twenty editions before his death, and, making the subject matter more and more elementary, he published in 1874 his *Elementary Lessons in Historical English Grammar*, and in the same year the *Primer of English Grammar*. F W

**Grammatical Study** - The grammar of the vernacular has not usually been regarded as a subject for scientific consideration in itself, but the views which have been held with respect to it from time to time, and which have guided instruction in the subject and the composition of textbooks intended for use in instruction, when they have not been merely utilitarian, have been rather a reflection of the prevailing modes of philosophical or linguistic thought in general. Moreover, methods of instruction in English grammar, as exemplified in the textbooks, have been extremely traditional, and have followed a few established models, with the result that though the number of English grammars is legion, they have added relatively little to the development of serious and independent theory with respect to the subject.

Two schools of thought in especial have exerted a powerful influence upon the conception of grammar, first, the systematic philosophic thought of the eighteenth century, and secondly, the modern scientific thought, as exhibited mainly in the sciences of psychology and historical linguistics. The principal inheritance of grammar from philosophy is to be found in the grammatical definition. The conventional definition of the sentence, for example, or of the parts of speech, is based upon the assumption of a correspondence between the forms of speech and the categories of a formal logical system. A grammatical statement of a language, according to this conception, would consist of a statement of all the modes of thought possible in that language. Several important consequences and corollaries have followed from this *a priori*, logical way of regarding the classifications of grammar. In the first place, if there is one logical form of thought to which the forms of speech each respectively belong, manifestly there is one and only one possible definition of a grammatical group of phenomena, and this definition is absolute and right. There thus has arisen in grammar the feeling for the dogmatic character of the definition or rule, and the desire to make the phenomena of language conform forcibly to the rule if they seem to differ from it. So much the worse for the language, says in effect the logical grammarian, if it does not conform to the fundamental laws of the mind. This has been the main defect of the logical method in grammar, that it has preferred a specious appearance of regularity and system to the actual variety and unsystematic wealth of detail of real speech. The

forms of speech do not fall into simple categories, but, as observation quickly shows, they overlap and often shift their functions in a way which can be described adequately only in the terms of a system too complex for practical grammar.

Disregarding the so-called "fundamental laws of the mind," the scientific grammarian has tended to approach the subject from an inductive point of view, and has studied the individual forms of speech in relation to their corresponding moments of mental activity, rather than in relation to any supposed permanent characteristics of the mind. The significance of the definitions, according to this conception of grammar, is something quite different from the significance of the definition according to the philosophical or logical method of systematizing language. The scientific grammarian regards his definition as merely a convenient summary statement of the facts he has observed. It has no final sanction of any sort, but is open to alteration and to extension as new facts are added to the field of observation. The spirit of this method of grammatical study is consequently not dogmatic, but is the spirit of all inductive science in which generalizations are regarded as the summary statements of accumulated details. It follows that the definition, rules, or generalizations which the grammarian of this way of thinking wishes to make must be definitions or generalizations of only such phenomena as those for whom his grammatical system is intended are capable of observing and understanding for themselves. A completely scientific grammar of English would neglect no phenomenon of the speech, no matter how insignificant intrinsically or how limited the extent of its use. The ideal of the philosophic grammarian is to formulate all the activities of the mind into logical definitions, and then to illustrate these definitions by means of examples taken from the practice of the language. The ideal of the scientific grammarian, as unattainable as that of the philosopher, but perhaps a safer guide in actual practice, is to observe all the phenomena of the language as they are exhibited in use, and then to arrive at such principles or rules as will come without misrepresentation of the phenomena upon which they are based. This ideal aim of the grammarian must necessarily be modified in practice to accord with the more limited purposes of teaching and the more limited capacities of students. No matter how elementary the effort, however, the evidence of the vast number of contemporary or older English grammars goes to show that one or other of these two conceptions was uppermost in the minds of the writers, either that the grammar presented illustrations of the observation of immutable, logical laws of thought, or that it was a series of observations, classified and designated on the basis of their similarities, the classification being subject to modification

according as the area of observation was increased or decreased. The grammars of the first type are represented by Murray's and by the large number of grammars which assume the position of arbiters of good use. The grammars of the second type, unfortunately not yet the prevailing one, are represented by modern historical grammars, the purpose of which is to make a descriptive statement of the past facts of the language, and also by an increasingly large number of practical school grammars written not from the point of view of dogmatic good use, but with the purpose of training the student in the observation and valuation of the processes of language. The earliest English grammars were written from the point of view of the Latin and for the purpose of making the study of the Latin easier.

During the larger part of the nineteenth century, grammar held — next to spelling — not only the principal place in English instruction, but, in the upper grades, the principal place in the curriculum of the elementary school. The two most famous grammars of the early days were Noah Webster's and Lindley Murray's, both published near the end of the eighteenth century. Murray's grammar became, like Webster's spelling book, the standard; and the authority of Lindley Murray was sufficient to settle any point of disputed usage or doubtful syntax.

The curriculum of the common schools included, up to the last quarter of the preceding century, little besides reading, spelling, arithmetic, geography, and grammar. In the upper grades grammar vied with arithmetic in the amount of time and energy devoted to it, and in the value and respect accorded to it in the schoolroom and in the community. To be known as a good "grammarian," that is, as a student versed in the grammatical rules as given in the textbook, and skillful in parsing and in syntactical analysis, was to win, in effect, a kind of intellectual preeminence. Moot questions of grammatical construction were often the subject of excited debate, like difficult, or "catch," problems in arithmetic. Grammar was, in brief, the intellectual jousting ground of many sharp and eager, though underfed, intellects. G P K

**Content and Nature of Grammar** — Diversity of purpose, of method, and of content are the most striking characteristics of modern English school grammars viewed as a whole. The constant features are discussions of the parts of speech, of inflections, and, to some extent, of syntax. Some grammars add phonetics, others the composition of words by prefixes and suffixes, or prosody, or the rules of spelling, or of paragraphing, or forms for letter writing, or symbols for proofreading, or tables of weights and measures, etc. This variety in the content of modern school grammars is partly due to the presence of survivals from older and outgrown conceptions of grammar.

The old-fashioned village grammar of general information, planned for students whose entire English training was obtained through the study of English grammar, accounts for some of the topics. Others, like prosody, for example, are merely survivals from the old Latin grammars. In the classical and Renaissance conception of grammar as an art comprehending the appreciation and practice of literature as well as the elementary rules of the language, prosody logically had a place. It survives now in grammars only because there is no other convenient place to put it. Of similar origin is the division of etymology, which is still used to describe a section of English grammar having to do with the forms of words, including inflections, derivation, and composition. In the old Latin school grammars, as for example in Lily, the two main divisions of the subject were etymology, *i.e.* accident, etc., and syntax, *i.e.* concord. But the modern sense of the word "etymology" is something very different from this traditional use of the word, and what the old grammars call etymology would now be called morphology.

An examination of those modern grammars, written by persons of some independence of purpose and of scholarship, shows that three main conceptions of the subject, mixed in varying proportions, are prevalent. The first is the conception of grammar as a guide to good use, the second as the study of the system of the language in its broadest meaning as an expression of thought, and third a narrower definition of the system of the language, corresponding practically to the usual popular understanding of the term "grammar." The conception of grammar as a guide to good use no longer enjoys the favor it once received. This conception is also in large measure an inheritance from the Latin grammar of the Renaissance, in which grammar was defined as "the art of correct speaking or writing." This theory was first taken over explicitly into English grammar by Bishop Lowth in his *Short Introduction to English Grammar* (1767). In his preface, Bishop Lowth declares that "the principal design of a Grammar of any Language is to teach us to express ourselves with propriety in that language, and to enable us to judge of every phrase and form of construction, whether it be right or not." In other words, according to this theory, the purpose of grammar is to serve as a handmaiden to the art of speaking and writing. In communities of mixed racial and social provenience, in which there exists a confused and uncertain use of the idiom in colloquial speech, as is the case, for example, in most American city schools, it is necessary to give much attention to drill in the details of propriety of expression. Yet the tendency of modern theory and practice, which seems to be in the right direction, is to place less stress upon good use as the main principle of the study of grammar. It is coming to be recognized

that the rules of use are so complex and so far beyond the grasp of the child that to place them in a grammar which makes pretense to a reasoned system is bound to end in confusion. Presented merely dogmatically, without attempt at rational or historical explanation, the rules of use find a more justifiable place in the study of written composition or in the drill of the daily colloquial intercourse of the classroom. Although the end, therefore, of inculcating good use may be to some extent attained by the study of grammar, it is now usually assumed that this end should be one of the by-products of such study, and not its main purpose and justification. Such being the case, the custom of introducing examples of bad use into the study of grammar is one of doubtful expediency. The safest rule seems to be to include in the system of elementary grammar only what is recognized as the normal use of educated people, with an exception perhaps in favor of occasional instances of divided use.

The two remaining theories concerning the teaching of grammar have this in common, that they both endeavor to approach the subject in a measurably scientific and systematic spirit. They differ widely, however, in the theoretical limits which they place upon the subject. In the broader conception of the two, the limits of grammar are made commensurate with those of the science of language, or the relations of speech to thought. Thus, according to one writer, "Grammar may be defined as the study of the relation between mental action and the forms of language expression" (Davenport and Emerson, *Principles of Grammar*, p. 1), the main stress being here placed upon logic. Another declares that "Grammar is a systematic description of the essential principles of a language or a group of languages. English grammar gives a systematic account of the English language" (Carpenter, *Principles of English Grammar*, pp. 1-5). A broad theoretical definition of this kind is manifestly impossible in practical execution. No elementary grammar can attempt to study in any systematic way all the principles, either logical or historical, which lie at the base of a language. Whitney (*Essentials*, p. III), with his usual wisdom, states the only position which the scientific study of elementary grammar can maintain. He avoids a positive theoretical definition of the subject, but announces his practical purpose to be "to put before the learner those matters which will best serve him as a preparation for further and deeper knowledge of his own language, for the study of other languages, and for that of language in general."

The study of elementary grammar, either as the science of language or as preliminary preparation to the science of language, is a way of regarding the subject which has arisen naturally from the modern science of linguistics. It would seem, however, that the content and purpose of the teaching of elementary grammar

should be determined by the possibilities and needs of elementary instruction rather than by scholarly theories of the subject. In answer to this conviction, we have a third conception of grammar, which still endeavors to be systematic, but does not try to cover the whole field of linguistics. According to this understanding of the subject, elementary grammar is defined as "an account of the relations which words bear to one another when they are put together in sentences" (Buehler, *A Modern English Grammar*, p. 11). Or again, it is "the science which treats of the nature of words (*i.e.* the parts of speech), their forms (inflections), and their uses and relations in the sentence" (Baskervill and Sewell, *English Grammar*, p. 12). A third definition makes grammar "the science which treats of the Forms and the 'constructions of words'" (*i.e.* of inflections and syntax) (Kittredge and Arnold, *The Mother Tongue*, Book II, p. xv-). Grammar, as thus defined, takes account chiefly of the relationships of words to each other in groups. The unity which it attempts to impress upon the mind of the student is the unity of the word group, and ultimately of the sentence. A unified conception of a science of language, either from the logical or historical point of view, is not implied in these treatments of the subject, and though historical and other considerations may be admitted, if it seems advisable to admit them, it should be recognized that the unity of the sentence is the essential element which determines both the content and method of such teaching of the elements of grammar. Thus limited, the subject becomes practically syntax.

In a strict application of the theory of the study of grammar as the syntax of the sentence, a number of features commonly included under the heads of grammar will be seen to be out of place. In the classification of the noun, for example, the distinctions of concrete and abstract, of common and proper, etc., have purely logical and not syntactical value. Some grammars give a class of "material nouns," glass, wood, iron, etc., which suggests to what extremes a logical classification of nouns could go. In the same way, the gender of nouns is of little syntactical significance. In the grammar of the earlier periods of the English language, when gender was still a grammatical, not merely a natural distinction in nouns, the rules of concord made gender very important syntactically. But in modern English the question of gender in nouns is raised only when the agreement of the personal pronoun of the third person singular with its antecedents is to be determined, and here also the feeling is for logical rather than formal grammatical agreement. The same principles apply to many of the subclassifications of the other parts of speech, *e.g.* of the adverb, as of time, place, manner, degree, distance, etc.; of the conjunction, as concessive, causal, temporal, local, etc.

In a rigid definition of grammar as the study of words in the context of the sentence, such logical subclassification can find a justifiable place only when they make clearer the functional nature of the part of speech in question.

The task of teaching elementary English grammar is harder than it would be if every syntactical construction told its meaning by the forms, or inflections, of its words. English, however, has lost practically all of its inflections, and it is in the necessity of apprehending function, whether with the aid of form or without it, that the teacher finds his main difficulty, as also his greatest opportunity. By a process of abstraction, words are taken up and discussed as parts of speech as though they could have meaning and function independent of their combinations with other words. In considering inflections, this abstract discussion is continued by associating with the noun, for example, the formal marks of numbers, with the pronoun the marks of numbers and case, with the verb the marks of person or tense, in each instance as though number, person, tense, etc., were characteristics which may have existence apart from context. These abstractions, however, are merely the way of approach to the vital organization of the parts of speech mutually dependent upon each other. Having analyzed the elements of speech, the student is then brought to synthesize them in the formation of speech. The language upon which study should be based obviously should not be too remote from the experience of the student—not puzzles of grammar, or the language of literary prose and poetry. It should be normal language of daily use, and the student should realize that the real life of language passes not only in the minds of authors and scholars, but in his own and in the mind of every one who uses the language.

The completed sentence is the largest term in which the language consciousness of the naive speaker or writer moves, and beyond this, in the group of sentences, in the paragraph, and in the essay, etc. As a whole, there is unity, but it is unity of an entirely different kind from the unity of the sentence. One may think and write the English language without the paragraph, but not without the sentence. The sentence is the necessary unit of expression, and the mastery of it entails at least a practical command over the English language. It is in this way that grammar, considered as the study of the sentence, connects with the study of the art of expression. It should be the result of the study of grammar that students become aware of the plastic nature of language, and although questions of effectiveness in speech are not primarily questions of grammar, they are close and material sequences of grammatical speculation. Though the conception of grammar as the study of the functions and the forms of words in sentence-forming combinations may seem narrow as

compared with the broad program of the science of language, it nevertheless leads to what is the practical end and reason for the existence of all language, the expression of thought by means of the grouping of words. The teacher of elementary grammar has no need to feel that he has set his mark too low in endeavoring to bring his students to an intelligent conception of what is meant by the sentence in the study and in the use of the English language.

**Methods of Teaching Grammar** -- The present tendency in the teaching of English grammar is greatly to contract the instruction, both in time and content, a tendency arising, first, from the current practice of requiring a new educational justification for all subjects in the curriculum, and, secondly, from the crowding of the curriculum by new subjects. In many of the best schools formal grammar occupies not more than three lessons per week for two years, and in some schools even less time. Many distinctions and classifications, such as are referred to above, are omitted, either as having no practical value or as being without meaning to an immature mind. The general value of grammar as formal discipline is now largely discredited. Its worth to the student seems to lie in three things: its occasional guidance in matters of incorrect or doubtful usage, its training in the process of thought as cast in the forms of the sentence, and its assistance to the student in the study of a foreign language. To these may be added its tendency to arouse intelligent interest in language as a subject worthy of intelligent attention, especially when some of the historical features have been incidentally introduced into the study.

The long-recognized difficulty of teaching grammar successfully is due mainly to its abstract nature. Young pupils do not easily or naturally grasp grammatical abstractions, hence the necessity for limiting the amount, for selecting those principles that are simplest or most necessary, for frequent repetition, for confining the work to intelligible sentences, for abundant drill and frequent repetitions, and for connecting grammatical study as closely as possible with the pupils' oral and written use of the language. Even under the best instruction it is to be expected that pupils will often err, often be confused, and generally forget much that they once knew rather well, for abstractions are neither clear nor permanent in most minds.

The order of procedure in the instruction has been under much discussion, two general plans being suggested: from the word to the sentence (the older, and formerly the invariable, plan), and from the sentence to the word. In the former the pupils first learned the parts of speech, that is, noun, verb, etc., with their definitions and with or without examples in sentences; that is, they began with the so-

called etymology. In the second plan the study begins with the sentence (*i.e.* with syntax), considering first the general subject and general predicate, then viewing the sentence as consisting of strict subject and strict predicate (noun and verb), each of them possibly with or without a modifying word or phrase, and so proceeding by steps of analysis to the ultimate elements, *i.e.* the words (see Barbour's *The Teaching of English Grammar*, 1901). Various modifications of this second plan, in combination with the first, are now in general use, textbooks and teachers differing mainly in the stages at which they introduce the detailed study of the various parts of speech. This plan makes it possible to introduce some of the simpler elements of grammar as early as the fifth or sixth year in connection with the pupil's writing, and so to prepare him gradually for the more difficult study of formal grammar in the textbook.

A considerable amount of drill is necessary in all teaching of grammar. But certain changes have been made in the matter and substance of drill. It is important to proceed not merely from the examples to the principles, but also from the principles to the examples, the pupils being required, for instance, not merely to identify adjective clauses and adjective phrases, but to write sentences containing these elements. Parsing, that is, identifying the part of speech of a word and pointing out its relations, has no longer the large place it once had. Its value is doubtful as a means to the real function of grammar, *i.e.* the study of the sentence, and its propriety or even possibility must often be questioned. There are many single words that cannot be parsed. They must be taken in connection with other words, as a group, before their relation to the sentence can be indicated. Nor is it permitted to change the forms of expression to bring words under the rules. Such a change only makes a new sentence. It must furthermore be noted that certain conventional explanations of construction were made before the study of English philology had explained their real origin. An example is the so-called "retained object" with the passive voice, as in the sentences *I was given a book* and in the phrase *one by one*. Many instances could be cited showing the disappearance of inflectional indications of agreement or concord, and other departures from the Latinized conceptions on which our older English grammars were based. (See Gould Brown, *Grammar of Grammars*, Introduction.)

In general, therefore, teachers at home in the subject are inclined to doubt the advisability of much "parsing." Drill in syntax has come to occupy a much more important place, and "diagramming" is still in favor as a short and convenient way of indicating relationships. In the study of both etymology and syntax the old logical conception is rapidly giving way before the more scientific view of

English as an idiomatic speech whose special features are to be explained only by a knowledge of their origins

One important question of method remains to be considered. How far should the study be inductive? We proceed in the main from examples to principles and definitions, but principles must be reinforced by, and reinterpreted in terms of, examples. Some of the more difficult conceptions, as those of verb phrase, conjunction, preposition, are best taught almost exclusively by examples

**GRAMMAR GRADES** — The elementary school normally covers eight years of work, which may be begun at about the age of six years. The upper four years of the elementary school are known as the grammar grades, as the lower four are called the primary grades. Sometimes, because of exceptional administrative conditions, the fifth year of school may be included among the primary grades, as in the case where a primary school building includes the first five years of work, or where these first five years of work are set off because the departmental system of instruction by specialized teachers does not cover more than the sixth, seventh, and eighth years. The grammar grades, while normally covering four years, may be four or eight in number, depending upon whether or not the graded system provides for annual or, as is the usual case, semi-annual promotions

**GRAMMAR-HIGH SCHOOLS** — A term used in the school laws of California to designate a two-year high school, to which state aid is given. Such schools represent the first two years of the regular high school, and are to be established where full four-year high schools are not as yet needed. The term corresponds in a general way to the term Township High School, as used in the upper Mis-

issippi Valley to designate short-course schools which have not been "accredited" or "commissioned" as full high schools. (See HIGH SCHOOLS, RURAL.)

**GRAMMAR SCHOOL** — To write the history of grammar schools would be to write the history of elementary and secondary education from their dim beginnings in Hellas in the fifth or sixth century B.C. to 1850, when the greater number and the chief of the secondary schools on both sides of the Atlantic were still called Grammar Schools. Even where the title has been dropped for that of Public School, Latin School, Academy, Gymnasium, High School, Lycée, Ginnasio, these are still essentially grammar schools, and, what is more, the chief of them still Greek Grammar Schools.

The term Grammar School (*γραμματεῖον*) simply meant a Letter School, a place in which letters (*γράμματα*), that is, spelling and reading, were taught. But it has always been found that it is impossible to teach even reading properly without teaching much more, and the term *grammata* soon came to connote an ever-widening circle of learning till it became identical with literature in its widest sense. Already in the sixth century B.C., the vases show the boys learning writing as well as reading, and standing up to say their repetition of Homer, while in later days they received prizes for public competitions, not only in "rhapsody," but in successive stages of recitation of tragic, comic, and lyric verse. Naturally, poets had to be explained and understood for effective recitation, and the whole of literary comment, the science of grammar, the art of scholarship, criticism, and composition was developed from the grammar school.

Grammar and the grammar school were developed at Alexandria, where the Macedonian variety of Doric-speaking students of Attic writers perhaps required more assistance from grammar proper. The grammar school was transplanted full grown to Rome. Plautus, c. 210 B.C., used the term in its Latin translation of *ludus literarius*. (For the development of this school, *ludus literarius*, and the later rhetoric schools, see ROMAN EDUCATION; QUINTILIAN; ENDOWMENTS, EDUCATIONAL.) A Greek grammar school had been set up by Livius Andronicus, a Greek, in 272 B.C. At Rome the early grammar schools were more advanced than those of Greece, where the grammar schools were confined to literary explanation and criticism, while according to Suetonius the early grammar schoolmasters at Rome also taught rhetoric and "many of their treatises include both sciences," i.e. grammar and rhetoric. In later days at Rome, as in Greece, the two were separated, the grammar school teaching the boys till about fourteen and confining themselves to literary construction, the rhetoric school including every study which could fit a youth to become a good

speaker Quintilian, whose *Institutes of Oratory* is the only complete ancient educational work which has come down to us, shows that the grammar school had extended its boundaries to include, for instance, the teaching of history and the elements of philosophy, leaving the rhetoric school to be more professionally and professedly a "talking shop." The grammar school and the rhetoric school were ubiquitous through the Roman Empire. From the end of the first century A.D. they came to be largely provided at the public expense by the municipalities or by endowments (see ENDOWMENTS, EDUCATIONAL), while the later Emperors, and particularly Gratian in 376, charged their maintenance on the *fiscus* or the rates and fixed the salaries payable. When the barbarian kingdoms began to settle down, the grammar schools became more than ever necessary, in a sense, for teaching Latin as the foreign tongue, in which new nations found their religion and their law enshrined and administered. While the rhetoric schools, therefore, disappeared, the grammar schools went on, and, so far as the higher studies of the rhetoric school were needed, they were studied in the grammar schools, which passed under the control of the bishops. It is difficult to say when they ceased to be public schools and became episcopal schools, if indeed it is possible to draw any such distinction, for the bishop seems to have stepped into the place of the civil magistrate in respect to public order generally as much as to education. (See BISHOPS' SCHOOLS.) The earliest mention of a school in England distinctly calls it a grammar school. It was when Bede (*Ecc. Hist.* iii, 15) related how in 631 Sigbert, King of the East English, who had been converted to Christianity when an exile in France, desiring to imitate what he had seen well arranged there, set up a school in which boys might be taught grammar (*litteris erudirentur*), and got masters and ushers for the purpose from Canterbury. Alcuin would no doubt have called the school of famous Cathedral York, which he describes a century later (731 to 780), a grammar school. For, though its curriculum included law, music, astronomy, geometry, arithmetic, and theology, yet grammar and rhetoric are put first, the master industriously giving to these the art of the science of grammar and pouring on those the rivers of rhetoric, while the writers on grammar from the Vergilian commentator, Servius, to Probus and Priscian bulked most largely in the school library. At the end of the eighth century (c. 796), Alcuin recommended his quondam pupil, the then archbishop, to separate the grammar school (*qui libros legant*) from the song and the writing schools (*qui cantilenas inseruiant, qui scribendi studio deputentur*). The current custom for bishops to maintain grammar schools at their sees was made general law by the canon of Pope Eugenius in 826,

ordering all bishops to maintain grammar schools (*studia literarum*) in which the principles of the liberal arts should be taught, an enactment repeated by Pope Gregory in a synod at Rome, c. 1073. It is stated in Asser's *Life of Alfred* (c. 1001) that the King's youngest son Ethelward was sent to the grammar school (*ludis literariæ disciplinæ*) with nearly all the noble children of the realm and many who were not noble, a statement which is at least rendered probable, and probably taken from the educational program set forth by Alfred himself in the introduction to his Translation of Gregory's *Pastoral Care*. Alfred (*qv*) desired that all the young English freemen should be set to learn to read English, and those who wanted to continue in learning and reach higher rank should learn Latin. Alfred the Great (*qv*) is credited with the establishment of grammar schools, while Ælfrie's (*qv*) *Saxon-Latin Grammar* (c. 1005), being excerpts from Priscian's grammar, purports to be a grammar as taught in the school of Ethelwold, Bishop of Winchester. So too the Danish king, Canute, is credited by his eleventh-century biographer with founding public schools (*publicas scholas*) to teach boys grammar (*litteris imbuendos*). In the school attached to the collegiate church of Waltham, founded by King Harold when earl, grammar and Latin verse-making were learnt. The earliest use of the actual words "grammar school," *scola grammatice*, as distinct from its Latin equivalent, *ludus literarum*, is in a charter of the last half of the twelfth century, in which Henry, Count of Eu and Lord of Hastings, confirmed the foundation by his grandfather Robert, Count of Eu, who received Hastings from the Conqueror, of the Collegiate Church of St. Mary in Hastings Castle and the division of its possessions into separate prebends among the several canons or prebendaries, including "Auscher's prebend to which belongs the keeping of the grammar school (*regimen scolæ grammatice*)," while "to Wyming's prebend" pertains "the keeping of the Song School (*regimen scolæ cantus*)." It is not clear whether Count Henry is quoting the words of Count Robert or translating them into the language of his own time. But it can hardly be doubted that the Warwick School, Gloucester School, Pontefract School, Thetford School, St. Paul's School, St. Alban's School, Huntingdon School, Dunstable School, and Reading School, — to mention some which are so called in extant grants of the latter part of the eleventh and first part of the twelfth century — would have meant the grammar schools of those places, just as in the present century they would bear the same meaning, though for the most part the masters aspire to drop the qualifying epithet and call them by the place name *tout court*. In the thirteenth to the nineteenth centuries inclusive it was thought more honorable to insert the qualifying epithet of

"grammar" school This became necessary in the thirteenth century to distinguish grammar schools from the schools of the higher faculties at the universities, and the Theological Schools, to which the schoolmasters of cathedral and collegiate church grammar schools, when they changed their name to the less known and intelligible, and therefore more magnificent title of Chancellor (*qv*), confined their ministrations. A notable illustration of the way in which the Cambridge School was shorn of its prestige and glory by the side of the university is to be found in the order made by the diocesan of Cambridge, the Bishop of Ely, in 1276. From this it appears that the Master of Glomery (*qv*) had still jurisdiction to hold legal pleas in which grammar scholars were concerned, as the Chancellor of the University had in those to which university students were parties. He too had a bedell or beadle to bear a mace before him, not only *honoris causa*, but also as the physical implement with which to enforce his jurisdiction, just as the Chancellor had, who was in fact only a higher school-master. Similarly the Canterbury grammar schoolmaster in the years 1310 to 1327 exercised jurisdiction in cases between his scholars and the laity, enforcing by excommunication the sentences he imposed as judge of his court, in school, sometimes expressing his acts as "done in Canterbury school," sometimes "in Canterbury Grammar School." In London, what was called in 1138 the "School of the Arches," or St Mary-le-Bow, appears in 1300 on the appointment of a master as "the Grammar School of the Church of St Mary-le-Bow or of the Arches." (See ARCHES, SCHOOL OF THE.) So at St Alban's, the school over which the famous Alexander Neckham (*qv*) presided in the thirteenth century as St Alban's School, is in 1309 called St Alban's Grammar School. In that year its master, sitting "as Judge of the law of the Grammar School of St Alban's," made statutes in and for it in quasi-regal style "by the unanimous consent of the Master and all the Bachelors" of it. He too exercised his jurisdiction over laymen as well as clerks, forbidding any one to assault or defame any of the scholars on pain of excommunication *ipso facto*, while if any one assaulted the master himself, not only was he excommunicated, but was also subjected to "salutary chastisement in the school from all the Bachelors of it, unless he had previously made satisfaction to God and the church." The common notion, derived chiefly from a misinterpreted passage in Richard of Bury's *Philobiblon* referring only to the masters of small village schools, that the grammar school master was of no importance, a person looked down on, is contradicted by these documents, which also correct the erroneous notions as to the limited character of the curriculum of these schools. No one could become a bachelor in St Alban's Grammar School unless he first

obtained from the master a proverb, on which, as a theme, he had to compose verses, prose, and rhyme (Leonine or rhyming Latin verses?) and also make an oration publicly in the schools. Nor was any bachelor coming from elsewhere to take a seat in the school, unless he had first been examined in the rules of grammar by examiners appointed by the master and was prepared to dispute publicly in the school on them "or any other subject put forward," just as in the university. At Beverley the newly created bachelors had to make presents of gloves to a large number of the officials of the minster, just as they did at Cambridge University. But the growth of the university seems to have stopped this practice of creating bachelors in grammar schools, and we hear no more of them after the fourteenth century.

While the universities competed with the grammar schools in their upper portions, the song schools, which became to a large extent also reading schools, competed with them for their lower boys. Thus at Warwick about 1316 the Dean and Chapter made statutes to define the provinces of the grammar and music schools, assigning the Donatists, or those learning the elementary parts of Latin grammar, the Donat, to the grammar school, while confirming the music master in the possession of those learning their first letters, the *grammata* of the original Greek grammar school. Similarly at Canterbury the parochial school, maintained by the rector in connection with St Martin's Church, was impeached by the rector or master of the Archbishop's or City Grammar School for competition with him in taking grammar scholars, and was after trial by jury found to be customarily entitled to take thirteen grammar scholars only, though it might receive an unlimited number in the alphabet, psalter (*ie* reading Latin), and singing. A century later, the grammar school-master at Saffron Walden obtained a decree from the Abbot as Ordinary of Walden prohibiting the priests of the chantries connected with the parish church from teaching grammar or any higher subjects than the alphabet and the graces (*alphabeticis et graciis*) *ie* the graces before and after meat, for long misinterpreted as *gracis*, and alleged to show a Greek-teaching school in 1425.

As some indication of what was learned in the grammar schools at this time, it may be mentioned that a feeble, or tattered (*debilis*) Horace was bought for the Merton Grammar School boys in 1348 for a half-penny, while several pairs of white tablets for reporting arguments cost 2½d, showing that the dialectic method was applied to grammar as to other subjects. The master of this school at the time was Master John Cornwall (see CORNWALL, JOHN). The successive attacks of the plague in the Black Death (*qv*) in 1349, the Second Plague in 1361, and less well known

but still destructive outbreaks in 1369 and 1380 made such havoc in the knowledge of Latin that special new endowments appeared necessary to restore it. Hence the great increase of endowed grammar schools (see *ENDOWMENTS, EDUCATIONAL*), of which Winchester College, founded in 1382, was the leading example. Never, perhaps, had the superior efficacy of grammar as "the foundation, gate and source of all the liberal arts" — the essential element of a liberal education — been more emphatically proclaimed than in its foundation charter. For the first time a grammar school was made the principal or indeed the sole object of a collegiate church, as important a step forward in educational provision as the foundation of the first collegiate church as a university college in Merton College had been a hundred years before. It is much to be regretted that the object and curriculum of a grammar school was so well understood at the time that the elaborate code of statutes made for "Sainte Marie College of Wynchester" in 1400 contains not a word as to the content of the curriculum, nor the method of teaching, but merely prescribes that candidates are to pass a competitive examination in the "Old Donat" and plain song for admission "to study in grammaticals or the art faculty or science of grammar." An equal parsimony of details is found in the numerous grammar schools endowed in connection with colleges, chantries, guilds, and hospitals from that time to the eve of the Reformation. Though three hundred and more of these grammar schools were founded or refounded, endowed or reendowed, very few of the foundation deeds or statutes have come down to us, but, judging from those which have come down, they would not have greatly enlightened us. The greatest and richest of all the free grammar schools, the College Roiall of Our Lady of Eton (*qv*), was a mere replica in its statutes, as in its foundation, of that of Our Lady of Winchester. Colet (*qv*) was no doubt expressing the sentiments of all, when in his statutes for the refounded and augmented St. Paul's School in 1518, he said, "what shall be taught . . . it passeth my wit to devyse and determyne in particuler." Nor did he unfortunately vouchsafe any details when he went on to say "in generall" that the scholars were to be "taught all way in good litterature" and to denounce the "barbary, corrupcion" and "*Laten adulterate*" which "ignorant blynde folis brought into this world," the "fylthynesce and abusyon" which "rayther may be called blotterature than litterature," and went on to demand the "olde Latyn spech, the veray Romaine tong" of Tully and Vergil, as found in St. Augustine, St. Jerome, Sedulus and Juvenecus, and other Latin Christian writers of the lower Empire. What, besides Alexander de Villa Dei's (*qv*) *Doctrinale*, or grammar in verse, was included in "Blotterature," we can only guess. Colet did not succeed in substi-

tuting the late Latin-Christians for the earlier classical authors in grammar schools in general, though he apparently revived them, as Milton's reading appears to show, at St. Paul's. The statutes of Cardinal Wolsey, for the grammar school of his college at Ipswich, made in 1528, are preserved; and a year or two later we have parts of the curriculum of Winchester and the whole of the curriculum of Eton as sent to Saffron Walden for adoption in the newly refounded and endowed grammar school there. These show that the *Latin Accidence* of Stanbridge, scholar of Winchester and Master of Magdalen College School, of which Wolsey had himself been master, with at Eton the grammar of Lily, first master of the refounded St. Paul's School, and at Winchester that of Sulpicius, a fifteenth-century schoolmaster at Rome, had superseded Donatus and Alexander de Villa Dei. The lower forms read the pseudo-Cato's *Moralia*, as their predecessors had done at Merton in 1308 and centuries before that, and Æsop's *Fables*, which were still in vogue at Highgate Grammar School in 1860. For the rest, they read Lucian's *Dialogues* (in Latin), Ovid's *Metamorphoses*, Terence, Cicero's *Paradoxes*, Vergil's *Eclogues* in the Fourth Form, in the Fifth, Sixth, and Seventh, Sallust, and Vergil's *Æneid*, Cicero's *Letters*, and Horace, with the figures of speech of Mosellanus, a German schoolmaster named Schade, of a pronouncedly Reformation type, scoffing at Saints and Saints' Days, and Erasmus' *Copia verborum*, which was much like Ælfrie's *Colloquy* and word books of the eighth century. Cæsar is the only author mentioned by Wolsey who does not appear in the Winchester and Eton curricula. Greek, it appears, was not taught, though it probably had been a little earlier under Holman.

Five years later the Reformation in England began with the dissolution of monasteries. Its educational first fruits are found in the statutes for the grammar schools attached to the cathedrals of the new foundation of Henry VIII, under the new deans and chapters in lieu of the old cathedral grammar schools, under the immediate cognizance of the bishops. There is no noticeable difference in the curriculum. The master is indeed called by the high-sounding name of *archididascalus*, instead of *Magister Informator* or *Magister scholarum*, and the second master, *hypodidascalus*, instead of *Ostianus* or Vice-monitor. Greek as well as Latin is now required of the master, though Latin only of the usher. The object of the foundation scholars, lodged, boarded, and clothed at the expense of the cathedral endowment, is expressed, as before, to be to obtain a fair knowledge of Latin grammar and to talk and write Latin. No Greek author is mentioned in the curriculum, which includes vaguely the chaste poets and the best historians, and in the Sixth or highest form Erasmus' *Copia* with "Horace and Cicero and

other authors of that class." In none of the re-foundations under Edward VI and Elizabeth is any inkling given of the curriculum contemplated beyond the direction that the newly constituted school is to "endure to all future time for the education, institution, and instruction of boys and youths in grammar" (See FREE SCHOOLS, EDWARD VI, ELIZABETHAN PERIOD IN ENGLISH EDUCATION, REFORMATION AND EDUCATION).

That Greek had by this time crept into the schools is shown only by the salvos of verses presented to the King when he visited Winchester and Eton, perhaps five per cent of which are in Greek. It is not till we come to the statutes made by Queen Elizabeth in 1560 for the grammar school attached to the Collegiate Church of the Blessed Peter of Westminster, which took the place of the abbey dissolved by Henry VIII and reinstated by Queen Mary, that any difference in subject or detailed curriculum is forthcoming. The duty of both master and usher, *ludimagister* and *præceptor*, is defined to be to teach Latin, Greek, and Hebrew grammar, *literæ humaniores*, poets and orators. Cato and Æsop still prevail in the lowest forms with Vives (*qv*), Terence and Sallust in the Third Form. In the Fourth Form Greek grammar appears with Lucian's *Dialogues* in Greek, in the Fifth Form, Isocrates and Plutarch; in the Sixth and Seventh, Demosthenes and Homer as well as Livy and Vergil. Only the Seventh Form was actually to be taught Hebrew, devoting the last hour between five and six every school day to Hebrew grammar with a reading in the Psalms in Greek and Hebrew. That Hebrew remained an integral and effective part of the curriculum at Westminster is clear from the evidence of Charles Hoole's *New Discovery of the Old Art of teaching school* (1659). He testifies that Westminster boys under Busby (*qv*) made orations and verses in Hebrew and also "Arabic and other oriental tongues" "to the amazement of most of their hearers." But though Hebrew was included in many school statutes up to the latter part of the seventeenth century, and Hoole includes it in his ideal school for three mornings a week, and Mills in 1741, in his *Pueritiæ formandæ artifex*, includes Hebrew and *Lips Prophetica* for those boys who "wished to be clerics," it never had real hold in the grammar schools. It is still taught to a limited extent at Merchant Taylor's School, reputed to be founded in 1560, the same year as the Elizabethan statutes were given to Westminster, and was traditionally taught a few years ago at Louth Grammar School in Lincolnshire. The net result of the Renaissance and Reformation on the curriculum and methods of grammar schools was little more than to place Greek in the same position as Latin, with more *éclat* attaching to a real knowledge of it, but less consequence attached and less effort made to attain that knowledge in the majority of pupils.

As to the class which attended the grammar schools, it is certain, notwithstanding oft-repeated assertions and commonly received notions to the contrary, that it was in the main the same as now, that is, the middle class, the younger sons of the nobility, including in that term the whole knightly class and squirearchy, the great and small landlords, the professional classes, which at first were almost entirely the common lawyers, as the medical men and the chancery and ecclesiastical lawyers were mostly clerks and ousted from matrimony, the merchants and tradesmen. The chief difference is that to this class since the Reformation new recruits came forth from above and from below, from the eldest sons of the landed classes and from select individuals of the working classes. In Alfred the Great's family, according to Asser, the eldest son was brought up in chivalry, in hunting, and the arts of war, with only so much literary instruction as to learn Saxon poems by heart and to read Saxon, while the youngest son was sent to the grammar school. This practice was followed in other noble families with few exceptions throughout the Middle Ages, up to the latter part of the sixteenth century, the tincture of literature being probably less in the tenth to the twelfth centuries than in the ninth, and growing as learning grew from the thirteenth century onwards. Throughout, the younger sons even of the noblest families went to grammar schools and acquired learning for the clerkly profession, which included not only bishops and priests, but the whole of the government services, diplomacy and the law, and, increasingly, *la haute commerce*. While William Rufus was a rude soldier, the younger son Henry was sent to school, and learned grammar, and, as William of Malmesbury mentions, when he became king, in all his wars and troubles never forgot his learning or to read books. The celebrated Abélard was the eldest son of a Breton knight and landowner. Thomas à Becket, who is expressly recorded as having passed through the school of the city of London, *i.e.* St Paul's School, before going to Paris University, was the son of a sheriff of London in the days when aldermen were still hereditary landowners and their offices territorial governments. On the other hand, Abbot Sampson of Bury, who also went to Paris University, was so poor that he could not pay the penny fee at Bury School, and at Paris eked out his living by carrying holy water. The archbishops and bishops, deans, archdeacons, and canons, who had all been at grammar schools, and after the twelfth century mostly at universities, were predominantly of noble birth. It was one of the grievances of the chapter of Lincoln, when Bishop Grosseteste (*qv*) wanted to "visit" them, that he was not a gentleman. When Henry III wanted to hang the Oxford scholars, recruited from the grammar schools, who had taken a leading part in the defense of North-

ampton in 1264, he was prevented by the barons of his own side, who protested that they were not going to have the blood of their sons and relations shed. A fourteenth-century list of the scholars of Paris University contains several counts and other nobles of various nations. The first "poor and needy scholars" of Winchester and of Eton were scions of well known county families, and the "Commoners" of Winchester, many of whom became scholars, were by statute bound to be "sons of the nobility" and were so in fact to within twenty years of the Reformation, when the lists cease. The Eton statutes excluded villeins, which included the majority of farmers and artisans. In 1447 the University of Oxford petitioned the Lord Say and also the House of Commons for their help to get Duke Humphrey's library for them, on the express ground that "many of your noble lineage and kinsmen have studied and shall hereafter in the said University." As a matter of fact, we know at least one relation of Lord Say who was a scholar of Winchester and fellow of New College, Oxford, and another who was a scholar of Eton. Macclesfield Grammar School was founded in 1503, expressly for "gentilmen's sonnes and other godemenn's children of the towne and contre therabouts." Colet ordered that his free scholars should provide wax candles for the school at the cost of their friends, when wax was a costly luxury. But perhaps the most striking testimony to the fact that the grammar schools were mostly frequented by the upper classes is the story of the admission of "poor scholars" on the new foundation of Canterbury Cathedral Grammar School in 1541. "More than one or two of the Commissioners would have none admitted but sons or younger brethren of gentlemen, as for others, husbandmen's children, they were more for the plough and to be artificers than to occupy the place of the learned sort." Archbishop Crammer, himself a scion of an ancient family in Nottinghamshire, had to stand up for the new idea of admitting the really poor and to protest not in favor of a majority of poor, but against "utterly" excluding them. At Canterbury, as at Worcester, the names of the scholars admitted are those mainly of the county families of Kent and Worcestershire. The admission of the working classes to participate in the schools was one of the new ideas of the revolution called the Reformation, and was one of the objects of the great increase in free, *i.e.* gratuitous, schools which followed it. At the same time another effect of the Renaissance and Reformation was the increase also of the uppermost classes in the grammar schools, though it was not till the seventeenth century that the eldest sons of great nobles are found in them. It was thought something of a scandal when, in 1569, the heir of Broughton castle, afterwards Lord Say and Sele, became a scholar of Winchester College as Founder's kin. It was not so regarded a century later when Sir Robert Wal-

pole was a "poor and needy" scholar of Eton. Until the distinction grew up in the eighteenth century between the great grammar schools which became known as public schools to which aristocracy flocked, and the smaller schools, the ordinary country grammar schools presented a real mixture of classes. The local nobility and gentry were found in them side by side with the local tradesmen and farmers. The sons of the former, passing on to the universities as commoners at Oxford or pensioners at Cambridge, often took the sons of the latter with them as servitors and sizars. This practice had descended from medieval times, when the servitors who were numbered with the *socii* of a rich man and lived in the same hostel were more often poor relations than of a lower class. The truth is that in the grammar schools, as in the church itself, and the professions as in other institutions, the progress has been from aristocracy and exclusion to democracy and the open door.

It was not considered after the Reformation any more than before that the grammar schools should teach anything but the classical languages. But the later years of Queen Elizabeth's reign were marked in many grammar schools, especially in the smaller country town, by the attempt to introduce English reading and writing and arithmetic in the lower parts of the grammar school under the usher. In the seventeenth century, especially during and after the commonwealth, it became almost a commonplace for the founders of small country grammar schools, of which there were a large number, to prescribe English grammar, and Latin only "if required." But it was not till close on the Commonwealth period itself that it occurred to people to found separate English schools or elementary schools, not grammar schools and commonly free (see FREE SCHOOLS). But the pathetic belief in the magic of Latin grammar as an indispensable talisman to unlock the doors of knowledge prevailed spasmodically even to the nineteenth century, even when the founders were clearly not thinking of providing education for the class who would go to the universities. But at Whittington in Derbyshire, founded in 1681 for "20 of the meanest and poorest mens' sons born in the parish," Latin as well as English and accounts were prescribed, at Lowestoft in Suffolk in 1735 a schoolmaster was to teach forty boys, with preference to fishermen's children of the parish, writing, reading, accounts, and Latin, at Wigglesworth in Yorkshire in 1789 a sum of £1000 was willed for the establishment of Clarke's Free School to teach children born in the township, or whose parents were legally settled there, Latin, English, writing, and accounts.

In the seventeenth century English began to take a more permanent part in the grammar schools, not that it was ever taught as a set subject and studied as a language or literature

in school, but the practice began of making English versions of Latin verse and English essays in classical subjects. At the end of the seventeenth century, though French began to be studied and French dictionaries and phrase-books to be written, it was taught in separate schools. Perhaps the earliest recorded instance of a French master teaching French in an ordinary grammar school known is that of a French usher at Croydon Grammar School, then part of Archbishop Whitgift's hospital, about 1717. But from the rather casual way in which he is first mentioned it is certain this was not the first instance of such ushers.

The unwillingness, and, according to legal decisions, the inability of the grammar schools to open their doors to modern subjects on a level with the ancient languages led to a marked decay in them during the eighteenth century. (See EIGHTEENTH CENTURY IN ENGLISH EDUCATION.) In 1805 in the Leeds Grammar School case (*Attorney-General vs. Whiteley*, 11 Ves. 241) Lord Chancellor Eldon (*q.v.*) stopped the efforts of the governors of the school to provide for the admission of modern subjects, holding that the Court had no authority to fill a school intended to "teach the learned languages grammatically" with "scholars learning the grammar and French languages, mathematics, and anything except Greek and Latin." A separate branch of the school to teach these subjects "might be very useful to the youth of Leeds, but could not possibly be represented as useful to the charity," and it was to the utility of the charity the court had to look. This decision stopped all reform of the grammar schools, except when, as in the case of Leeds itself, the endowment was large enough to go to the cost of a private act of Parliament. A generation later the Grammar Schools Act of 1840 overruled the decision and enabled the court to widen the curriculum, but only by the expensive process of a lawsuit. It took another generation before by the Endowed Schools Act, 1869 (*q.v.*), a body of Endowed Schools Commissioners was instituted to create more or less popularly elective governing bodies and to introduce natural science and modern languages. This had to be done by separate schemes in each case, frequently opposed in Parliament on political grounds. But now there are many grammar schools, in which grammar forms a very small part of the whole curriculum, which do not teach Greek at all, and in which it is even possible to escape Latin altogether. On the other hand, those which have been most successfully reformed in their government and have in view the preparing of boys for the universities retained a greater but more efficient instruction in classics, such as Sherborne in Dorsetshire, Sedburgh in Yorkshire, two of the earliest of the so-called Free Grammar Schools of King Edward VI, Derby and Ipswich, have dropped the word "grammar" and in imitation of Rugby, which was one of

the earliest to do so, call themselves simply Sherborne or Sedburgh School, after the name of their place, and would describe themselves as Public Schools (*q.v.*), almost in contradistinction to grammar schools. The latter term, however, has been retained, and is still used in schools in some of the great manufacturing towns like Leeds and Manchester. A F L

See articles on individual schools, *e.g.* ETON, HARROW, ST. PAUL'S, PUBLIC SCHOOLS, ENGLAND, EDUCATION IN, under Secondary Education.

**Present Position** -- A classification of English secondary schools is a matter of some difficulty. Many factors which are extraneous to education enter in to complicate the question. But the following three broad divisions may be made: (1) Those schools which are known as the Public Schools *par excellence*, most of these will receive separate treatment (*e.g.* Winchester, Eton, Harrow, Rugby, etc.). And since the Public Schools have established a tradition, an account of their general organization and spirit will be given under PUBLIC SCHOOLS. (2) A wide middle division including day and boarding schools, some accepting a government grant, some not, all charging fees, and the majority developed out of old foundations. (See ENDOWMENTS; ENDOWED SCHOOLS ACT.) (3) The third class of schools consist of those recently founded and maintained by local authorities and supported by government grants, taking pupils as a rule direct from elementary schools and keeping them for about four years. For these see ENGLAND, EDUCATION IN.

Here only those schools which fall into the second division are treated. Generally these schools are attended by the children of the middle classes, and with the exception of those who hold scholarships or free places all pupils pay fees which vary in amount from £12 to £24 in day schools and £75 to £120 in boarding schools. While it has been found convenient to group these schools under the caption of Grammar Schools, the titles vary widely. With many the term "College" has found great popularity in imitation of true collegiate schools like Eton (see, however, COLLEGE, ENGLISH), others merely bear the place name, and others again retain the title of Grammar School. The organization of all the schools is approximately the same. While some may receive pupils at the age of nine or ten, secondary work generally begins at the age of twelve, the pupils receiving their preliminary education in elementary or in special preparatory schools, and continues up to nineteen, although there is usually a great leakage at sixteen. The schools are usually divided into modern and classical sides, the former prepares boys for practical and commercial life as soon as they leave school, or in some cases for the universities, the latter for the universities and the professions. In some schools all pupils receive a common basis in a "junior school," and bifurcation takes place

## GRAMMAR SCHOOL

in the senior school at the age of thirteen or fourteen. In a few cases provision is made for special science and mathematical sides, for special preparation for army examinations, etc. The schools are organized in forms (*q v*), generally on a basis of six, and each form is under a form master who has general charge of pupils in his class, while for certain subjects, such as science and mathematics, there are specialists. For the influence of examinations on the work of English schools, see under that topic. For the social organization see ATHLETICS, EDUCATIONAL, BOARDING SCHOOLS; DORMITORIES; PUBLIC SCHOOLS; FAGGING, PREFECTS, STUDENT LIFE; etc.

The following schools taken from the *Public Schools Yearbook* (1911) may be regarded as representative. The basis of selection is the same as for membership of the Headmasters' Conference — namely, number of pupils in the school (one hundred boys at least), number of former pupils resident as undergraduates at Oxford and Cambridge (ten at least), and number of boys sent up to the universities annually (five or six at least). The nine great Public Schools are left for separate treatment. The dates of foundation in the following list are based on Leach

## GRAMMAR SCHOOL

	DATE OF FOUNDATION	NUMBER OF PUPILS	NUMBER OF MASTERS
Abingdon School	1563 (re-founded)	120	10
Aldenham School	1597	210	17

**GRAMMAR, STUDY OF** — See GRAMMAR, ENGLISH, ENGLISH USAGE, GREEK LANGUAGE AND LITERATURE, LATIN LANGUAGE AND LITERATURE

**GRAMMATEUS** (Heinrich Schreiber, or Henricus Scriptor, whence the Latinized Greek form of Grammateus) — Mathematician, was born at Erfurt, at least as early as 1496, and describes himself in one of his works as *Heinrich Grammateus von Erfurt der sieben freien kunsten Meyster*. He was a student at Cracow and at the University of Vienna (1507), and was well known as a teacher, and also as a lecturer in the university where he was educated. His publications include an arithmetic, *Rechenbuchlin*, that appeared in 1518, with subsequent editions in 1535, 1544, 1554, and 1572. He also published the following *Algorithmus proportionum*, in which was included some work in the theory of music (Cracow, 1514), *Libellus de compositione regularum pro vasorum mensuratione* (Vienna, 1518), *Behend und khunstlich Rechnung nach der Regel und weltsch practick* (Nurnberg, 1521), *Algorismus de integris Regula de tri cum exemplis* (Erfurt, 1523), *Eyn kurtz neue Rechen unnd Visynbuechleyyn* (Erfurt, 1523). Rudolff (*qv*) learned algebra from Grammateus, for he records his thanks to him in these words: *Ich hab von meister Heinrichen so Grammateus genennt der Coss anfangklichen bericht empfangen. Sag im darumb danck*. D E S

**GRANADA UNIVERSITY** — See SPAIN, EDUCATION IN

**GRAND ISLAND COLLEGE, GRAND ISLAND, NEB** — A coeducational institution maintaining academic, collegiate, commercial, and music departments. The entrance requirements to the college are equivalent to the work of a high school. The college confers the degree of A B on completion of the requisite courses. There is a faculty of twenty-five instructors.

**GRANGER, THOMAS** — Writer of a Latin grammar, 1616, and a logic, 1620. The grammar is entitled *Syntagma Grammaticum, or an easie and methodicall explanation of Lillie's Grammar, whereby the misterie of this Art is more plainly set forth, both for the better helpe of all schoole-masters, in the true order of teaching, and the schollers far more easie attainment of the Latine tongue*, 1616. Granger was an M A of Peterhouse College, Cambridge, apparently minister at Butterwick, near Boston, in Lincolnshire. His grammar is of importance on account of the Epistle to the Reader, containing "the generall Theorike, or true grounds of teaching." In this treatise Granger points out that commonly doubtfulness and confusion exist in teacher and scholar, unless he is full master of his subject and understands child nature. Granger has a clear insight into the causes of confusion and doubtfulness in the child. He understands that the psychology of the child is different from that of the man, and goes on to point out the differences in a very modern spirit. Granger anticipates something of the doctrine of self-activity. "The scholar must attain to learning by his own study, industry, diligence and exercise, *using his master as a help, as a nurse, or matrice*."

In 1620 Granger published *Syntagma Logicum -- or the Divine Logike*. This was a logic for divines in "the practice of preaching" and for the help of "judicious hearers" and "generally for all." It is dedicated to Bacon. The work is founded on Ramus (*qv*), the great reformer of logic, with modern applications. Granger supplies scriptural and theological illustrations of logic, as Fraunce (*qv*) had supplied English poetical and legal illustrations. F W

**GRANT, CHARLES** (1746-1827) — Statesman and philanthropist, born in Invernesshire. He was early taken by an uncle to India, where he entered the service of the East India Company, with whom he attained a position of great importance and influence. He interested himself greatly in the need for the social betterment of the natives, and never tired of sending to England suggestions for the increased estab-

lishment of missions in India. On his return to England he was instrumental in founding the Church Missionary Society (1799) and the British and Foreign Bible Society (1804). His treatise, *Observations on the State of Society among the Asiatic Subjects of Great Britain particularly with Respect to Morals, and on the Means of Improving it* (1813), led to the appointment by Parliament of a Bishop of Calcutta with jurisdiction over India and Ceylon, and to the grant of a lac of rupees (\$50,000) for promoting education. He drew attention, also, to the need of industrial training in India. Grant was also the originator of a plan for the education of young civil servants of the East India Company, which resulted in the establishment in 1805 of the East India College at Haileyburg. (See PUBLIC SERVICE, TRAINING FOR.) He sat in Parliament from 1802 to 1818 as member for his native county.

MORRIS, H. *The Life of Charles Grant* (London, 1904.)

**GRANT, ZILPAH** — See BANISTER, ZILPAH GRANT.

**GRANTHAM, THOMAS** (d. 1664) — A clergyman who on sequestration of his parsonage became a private schoolmaster, an advocate of a speedy way of teaching the Hebrew, Greek, and Latin tongues, and the determined opponent of corporal punishment. He appears to have belonged to a Lincolnshire family and to have studied at Oxford from 1628 to 1630 and at Cambridge (Peterhouse, M.A. 1634). Before 1644 he was teaching in Bow Lane, and wrote his *Brainbreakers Breaker* (*Μημοφθοροπαίκτης*) in which he protests vigorously against the severity of schoolmasters. Grantham gives a picture of the school teaching of the times, in which he attacks the weakness of teaching grammar by rote in an unintelligible language. Grantham sought to teach grammar rules understandingly "and by often applying them, the rules come without book whether they will or no." Still more remarkable was Grantham in his *Brainbreakers Breaker newly broke out again* in 1649-1650. In it he says: "A boy may easily learn a thousand words in ten days, that is, a hundred words in a day." Grantham proposes as remedy that all the revenues of the free grammar schools should be taken from them and placed in the hands of a treasurer, and only those schoolmasters who proved their ability to teach well should receive the public money. On one occasion, one of Grantham's challenges against a London public school was accepted and judgment given in favor of Grantham.

Grantham also wrote *Animadversions on Camden's Greek Grammar*, dealing with his favorite topic of the folly of learning grammar by rote, and in 1644 he wrote *A Discourse in Derision of the Teaching in Free Schools and*

*other common Schools*, in which he introduces three ordinary masters of Free Schools, a citizen, a country gentleman, a traveler, and himself, "Professor of the Greek and Latin Tongues in London." In 1660 he translated three books of Homer's *Iliad* into English. F. W.

**GRAPH** — A term used in algebra to refer to the representation of an equation by the methods of analytic geometry ( $q.v.$ ), and occasionally to refer to other line and surface representations of functions. The introduction of this topic into elementary algebra is recent. As in all such cases, there have been three periods in this introduction: (1) the period of adoption for the purpose of filling the gap left by the omission of some obsolete topic, (2) the period of extravagant and ill-considered use of a novelty, (3) the period of reaction and of investigation of the real merits of the theory. From the educational standpoint the greatest value of the graph lies in its power of showing visually the number and nature of the roots of an equation. For elementary purposes, as a means of finding the actual roots of an equation, its value is slight, although in the computation of the roots of a numerically higher equation it has of late been shown to be very useful. Its value in showing the functional relation of algebraic expressions is also great, and is coming to be recognized.

In elementary algebra it is desirable to introduce curve tracing as an aid in the study of the negative number. This work also offers an opportunity of showing the change in a function of a variable as the variable changes. It may next be introduced in connection with the study of simultaneous equations of the first degree in two variables. Here there are four types that may advantageously be considered: (1) Two simultaneous equations such as  $x + 7y = 15$ ,  $9x - 3y = 3$ . In this case the lines will intersect, and the result is a visual illustration of the fact that two such equations have, in general, a root, and that only one root is possible. (2) Two inconsistent equations such as  $6x - 9y = 7$ , and  $4x - 6y = 5$ . In this case the lines will be parallel, and the student sees that there is no point in common, and hence that two such equations in two unknowns are not necessarily simultaneous. (3) Two identical equations, such as  $6x + 9y = 12$ , and  $4x + 6y = 8$ . Here the two lines are identical, and the student sees that there is an infinite number of points on the two lines, and hence that there is an infinite number of values of  $x$  and  $y$  that will satisfy the two equations. (4) Three or more simultaneous equations in two unknowns, such as  $x + y = 5$ ,  $2x - y = 1$ ,  $7x + 4y = 26$ . Here

## GRAPHIC CURVE

the three lines pass through the common point (2, 3), and the student sees that in general three such equations have one common root, but that in a special case the lines may be concurrent and the equations indeterminate. The next use of the graph is found in the study of quadratics. Here the use is twofold: (1) In the study of a single quadratic equation in one unknown, the graph shows clearly the number of roots to be expected, the fact that imaginary roots enter in pairs, and the meaning of equal roots. (2) In the study of two quadratics involving two unknowns, or of one quadratic and one linear equation, the graph shows the number of roots to be expected, and the possibilities as to the nature of the roots. For example, a straight line cuts a conic in two points, and hence we expect two roots in solving a system consisting of a quadratic and a linear equation. Two conics, however, intersect in four points, and hence we expect four roots. The graph shows how two of these roots may be identical (the conics being tangent), or how two imaginaries may enter at the same instant, and all this makes an impression on the student's mind that the mere analytic proof does not make.

Used in this spirit, a reasonable study of graphs is desirable. Carried beyond these limits, the work usually degenerates into a formalism without object and without real interest.

D E S

**GRAPHIC CURVE** — A term applied to a line the characteristics of which indicate to the eye the relationship which two variable quantities sustain to each other as either the one or the other is increased or diminished. In order to determine this curve, two lines of reference, called axes, are drawn perpendicular to each other. A number of corresponding values of the two variables are obtained, and for each pair of values a point is plotted, the perpendicular distances of which from the two axes are representative of each of the two variables in that calculation. After a number of such points are plotted, it is usually possible to draw through them a line which will indicate the general character of the relationship between the variables involved. One of the best known of the graphic curves is that illustrating Weber's law, or the psychophysical law of the relationship between the intensity of stimuli and the intensity of corresponding sensations. It is found that in order to get any sensation at all the stimulus must be considerable. After this, as the stimulus is increased, the intensity of the sensation increases at first very rapidly, then more slowly, until at last further increase in the stimulus produces no result on the intensity of the sensation. In general, in order to produce an appreciable increase in the intensity of the sensation the intensity of the stimulus must be increased by a certain proportion of itself. The law may be pictured by the

## GRAPHIC CURVE

following graphic curve (Fig. 1). Distance measured on  $OX$  indicates intensity of stimulus. Distance measured on  $OY$  indicates

FIG. 1

intensity of sensation. Intensity  $Ob$  of stimulus corresponds to intensity  $Oa$  of sensation. Both are represented by point  $p$  on the curve. The curve in general resembles a parabola.

Graphic curves may vary from straight lines to curves of great irregularity. One of the simplest types is the *curve of distribution*, brought into prominence in psychological statistics by Sir Francis Galton ( $qv$ ). It represents the number of individuals of a group who represent each of the various existing differences in reference to any characteristic. For example, in a given fairly homogeneous population, there will be very few very short men, very few very tall men, and, as we approach the average height from either extreme, the number of individuals who correspond to the successive measurements will at first increase slowly, then more rapidly. The general form of the normal curve of distribution is as follows (Fig. 2). Distance measured on  $OX$

FIG. 2

indicates the amount of the characteristics in question. Distance measured on  $OY$  indicates number of individuals.

In reference to such distributions three values are of importance. These are the *average*, which is obtained by adding all the measurements together and dividing by the number of individuals concerned, the *median*, which represents the measurement above or below which 50 per cent of all the individual measurements lie, and the *mode*, or the measurement represented by the greatest number of individuals. It is interesting to note that average, median, and mode may in the same case represent different values, a fact which the form of the curve will readily display.

If a population, instead of being homogeneous, is divided, for example, into two groups which vary considerably from each other in reference

to the trait in question, this fact will be shown by a deviation from the normal curve of distribution. A population made up of two races, one considerably taller than the other, would be apt to be represented by a curve sagging at the center, as in Fig 3. Here the modes  $m$

FIG 3

and  $m'$  of the two racial groups would vary considerably from each other, producing the effect indicated.

Again, if some selective agency tends to destroy those who vary either above or below the normal, the curve will exhibit this influence by falling off abruptly on the side affected, and

FIG 4

representing what is known as a skew distribution, as in Fig 4.

Another simple type of graphic curve may be called the *curve of fluctuation*. In this the measurements on one axis represent intervals of time, while those made on the other represent the fluctuating values. The rate of growth in height or weight or of advance in any mental trait may thus be represented to the eye. Here the curves tend in one direction, but where health or school attendance or amount of improvement is represented, they are likely to rise and fall.

**Correlation** — Both the curve of distribution and that of growth or fluctuation indicate correlation. In the one case, a measurement is correlated with the number of individuals who represent it; in the other, with the time of occurrence of the fact that it indicates. The special character of the two curves differentiates them from the curve which represents the relation of two characteristics without reference to number of individuals or time of occurrence. This curve may, therefore, not inappropriately be given the title *curve of correlation*. The curve illustrating Weber's Law is an example of this type.

To plot a curve of correlation one trait must be taken as a basis, and the individuals representing successive measurements in this trait must be grouped together. Then the average measurement of each group in respect to the

other trait must be found. These successive averages must then be plotted and the curve drawn through them. It is evident that the curve will progress regularly in the direction of increase in the basal trait. Ordinarily such regular progress will not be discovered in refer-

FIG 5

ence to the averages representing the second trait. Thus the curve will fluctuate as in Fig 5. While in general there is progress in reference to the averages of the second trait, this progress is not uniform. Careful reflection, however, will make it evident that if enough cases are obtained the irregularities will be likely to disappear and that we shall have left a curve or straight line which will indicate the amount and character of the correlation or the lack of correlation between the two traits in question. Suppose, for example, the correlation between ability in mathematics and ability in classics were being

calculated. Let degree of mathematical ability be measured on  $OX$ , where  $O$  represents the minimum and  $X$  the maximum ability. Let degree of ability in classics be measured similarly on  $OY$ . Perfect correlation between the two powers would be represented by Fig 6. Every indi-

FIG 6.

vidual will occupy the same relative position in reference both to mathematical and to classical ability. On the other hand, if there

FIG 7

be no correlation, every group in reference to mathematical ability would in classical ability tend to show about the same mediocre average. The curve would then be parallel to  $OX$ , as

indicated in Fig 7. A curve of partial correlation would be represented in Fig 8, of per-

Fig 8

fect reverse correlation in Fig 9. Here as one ability increases, the other diminishes.

**Average Deviation** — It is evident that except where there is perfect correlation the curve does not enable us to place any individual in regard to one trait when his position in regard to another is known. When, however, the average deviation of the individual

Fig 9.

measurements from the averages that are represented by the curve are calculated, approximate prediction becomes possible. We can say that the chances are even that the position of any individual in one trait will not vary more than the amount of the average deviation from the place in the curve which is assigned to it by virtue of its rating in reference to the other trait.

The accurate determination of degrees of correlation is a matter of somewhat complicated mathematical analysis. For an adequate treatment of this subject the reader is referred to Thorndike's *Mental and Social Measurements*. The graphic curve is not intended as a basis for predictive calculation, but rather to exhibit a relationship in a form readily to be apprehended. It is evident that for this purpose it has great value in educational theory and practice. In this field the calculation of distribution and variation, of growth and fluctuation, or of correlation, whether in reference to mental or physical abilities, the effects of this or that educational method or condition, of school practices, or of a multitude of other factors concerned in education, is being recognized as of the greatest importance. In order to display the results of these calculations in a form easily grasped, the graphic curve is of very great value.

It is interesting to note that the use of axes of reference by relation to which the corresponding values of two variables can be determined was invented by Des Cartes ( $qv$ ) as a means of applying algebra to geometry. The

coordinate geometry reduces a visible geometric form to an abstract quantitative relationship. The graphic curve reverses this process, and puts the abstract quantitative relationship in a concrete visible geometrical form.

**GRASER, JOHANN BAPTIST (1766–1841)**

— A distinguished German educational writer, born in Eltman, Bavaria. He studied in Bamberg and Wurzburg, where at the age of twenty he became doctor of philosophy. He entered the priesthood, and was appointed prefect of the theological seminary at Wurzburg. After some experience as teacher and university professor he went in 1804 to Bamberg as school councillor (*Schulrat*). In 1810 he was transferred to a similar position in Bayreuth, which he filled up to the time of retirement in 1821. A monument was erected to him in Bayreuth by the teachers of Upper Franconia.

Graser's pedagogical theory was based on the philosophy of Schelling. He considers as the chief aim of education the development of the "divinity" in man. Education should make man conscious of his divine origin, and should cause him so to think and act as to make himself worthy of this origin. Graser also deserved credit for the introduction of a new method of elementary instruction by which reading and writing were taught together (*Schreiblese-methode*). The observations which he made in the teaching of reading directed his attention to the education of deaf-mutes. Through his efforts courses for the instruction of deaf-mutes were introduced in many German teachers' seminaries. Graser's chief works are:

*Divinität oder das Prinzip der einzig wahren Menschenerziehung* (Divinity, or the principle of the only true human education, 1830), *Elementarschule fürs Leben* (Elementary School, a preparation for life, 1831), *Der durch Gesicht und Tonsprache der Menschheit wiedergegebene Taubstumme* (The deaf mute restored to humanity through visual observations and oral language, 1829) F M

**GRAY, ASA** (1810–1888) — Scientist and textbook author, was graduated at the Fairfield College of Physicians and was professor in Harvard College from 1842 to 1873. Author of textbooks in botany and physiology.

W S M

**GRAY, THOMAS** (1716–1770) — Poet and scholar; he showed remarkable versatility, although in his student days he chafed so strongly against academic regulations and prescriptions as to leave Cambridge without a degree. Botany, zoology, history, language, archaeology formed the chief subjects of his studies. His most interesting contribution on education was the poem, *The Alliance of Education and Government*, which was unfortunately never finished. In it the poet pleads for “the necessary alliance between a good form of government and a good mode of education” (Mason). Apparently Gray abandoned the poem because he found a much better treatment of the subject in Montesquieu’s *L’Esprit des Loix*. The introduction of this poem, like several stanzas of the *Elegy Written in a Country Churchyard*, is a plea for educational opportunity for the “village Hampden” or the “mute, inglorious Milton.”

But Knowledge to their eyes her ample page,  
Rich with the spoils of time, did ne’er unroll

Gray’s first printed poem was the *Ode on a distant Prospect of Eton College*, which, while giving a picture of the Eton of his day, takes at the same time a somewhat pessimistic view of the joy and carelessness of youth, ignorant of the world before them.

**GRAZ, THE IMPERIAL ROYAL CHARLES-FRANCIS UNIVERSITY OF** — Like several other Austrian universities, the University of Graz, located in the capital of Styria, owes its origin to a Jesuit College, the college at Graz having been founded in 1573 by Archduke Charles. Soon afterwards a Latin school was

added to the college, this step being followed in 1585 by the organization of a university, which was formally opened in the following year, and remained under the control of the Society of Jesus until the dissolution of the Jesuit order under Empress Maria Theresa in 1773. The institution consisted at first of only two faculties, those of theology and philosophy, although the Jesuit College was looked upon as a separate *Facultas humanistica sive linguarum*. The original university building was completed in 1609, and remained in use until 1895, when a new building was dedicated. The first professorship in medicine dates back to 1774, and five years later a faculty of law was established. Emperor Joseph II lowered the tone of the institution, which by 1713 boasted of an enrollment of 1350 students, by degrading it into a lyceum, as a result of which the student body diminished rapidly in numbers until the university privileges were restored in 1826. The faculty of philosophy was reorganized in 1849, the medical faculty fourteen years later, the university at the present day possessing the traditional four faculties, the theological faculty being of course Catholic. There were 2074 students in attendance in the winter semester of 1909–1910, of whom almost half were enrolled in the faculty of law. The University Library, founded in 1586, contains about 250,000 volumes and almost 2000 manuscripts. Graz is also the seat of an Imperial Royal Technical School, which attracted 725 students in the winter semester of 1909–1910. R T, J1

**GRÉARD, CLEMENT VALLERY OCTAVE** (1828–1904) — French educator, born at Vire, and a friend of Prévost-Paradol. He was appointed an academy inspector by Duruy (*q v*), director of education in the department of the Seine, by Baron Haussmann, and vice-rector of the Academy of Paris by Jules Ferry to succeed Ad Mourier. He devoted himself to realizing in administration the greater part of the reforms elaborated and the progress begun by the great ministers of public instruction. Retiring in 1902, he died in 1904. Gréard was an administrator ready to put into practice the instructions of all the ministers, anxious for his reputation and standing, a man of energy, he could at times exercise, as a teacher expressed it, the suppleness of an Italian cardinal. In elementary education he demanded orderliness in buildings and equipment, proper care of the pupils’ exercise books, methodical instruction, etc. In the secondary

field he strove to apply to the *lycées* for girls some of the ideas of Fénelon and Madame de Maintenon, and in the *lycées* for boys he took as his guide the reforms suggested by H. Marion (*q.v.*) Opposed on principle to the boarding school, which he accepted as an administrator, he tried to establish some *lycées* in the country round Paris; the attempt failed within the University, but succeeded outside.

The chief works of Gréard are *Le Morale de Plutarque* (1866); *Lettres d'Abélard et d'Héloïse* (1868); *L'Organisation pédagogique des Ecoles de la Seine* (1868); *L'Instruction primaire à Paris* (1871), *La Législation de l'Enseignement primaire en France depuis 1789* (1900); *L'Enseignement secondaire des Filles* (1887), *Éloge de M. de Falloux* (1888), *Éducation et Instruction* (1888 and 1900), etc. J. P.

**GREAT BRITAIN** — See ENGLAND, EDUCATION IN, IRELAND, EDUCATION IN, SCOTLAND, EDUCATION IN, WALES, EDUCATION IN

**GREAT DIDACTIC** — See COMENIUS

**GREATEST COMMON DIVISOR** — The greatest number that will divide two or more given numbers, producing an integral quotient, is called their greatest common divisor. Formerly the greatest common divisor had a prominent place in the teaching of arithmetic, but now this position has been lost, the subject having value only in the theory of numbers (*q.v.*) The reason for its former prominence is easily seen when we consider the nature of the common fraction of the Middle Ages and early Renaissance. (See FRACTIONS.) For example, in reducing a fraction like  $\frac{2257}{3599}$  to lowest terms, for the purpose of operating with it or of expressing some result in simpler form, the factors to be suppressed are not at once evident. It therefore becomes necessary to find the greatest common divisor by a form that is given in Euclid's *Elements*, and therefore known as the Euclidean method. This is illustrated in the following operation:—

$$\begin{array}{r}
 2257 \overline{) 3599} (1 \\
 \underline{2257} \phantom{00} \\
 1342 \phantom{00} \\
 \underline{1342} \phantom{00} \\
 915 \phantom{00} \\
 \underline{915} \phantom{00} \\
 427 \phantom{00} \\
 \underline{427} \phantom{00} \\
 61 \phantom{00} \\
 \underline{61} \phantom{00} \\
 427 \phantom{00} \\
 \underline{427} \phantom{00} \\
 0
 \end{array}$$

The proof that 61 is the greatest common divisor of 2257 and 3599 depends upon two principles: (1) A divisor of any number is a divisor of any multiple of the number; (2) A common divisor of each of two numbers is a divisor of the sum or the difference of any multiples of the numbers.

Educationally the subject has lost its significance, since the general acceptance of the decimal fraction. The common fraction now being limited to simple forms, we no longer need to reduce difficult fractions to lowest terms, at least in ordinary business and science. The mere suppression of factors by inspection suffices for such cases of reduction as practically occur. This being the case, it is somewhat absurd that greatest common divisor should be taught by factoring, as is commonly the case at present. Since the only time when we practically need to use the greatest common divisor is when we cannot readily factor two numbers, to find the greatest common divisor by factoring is to find it under conditions that are never met. If we can easily factor, we can cancel factors from the terms of a fraction without taking the trouble to find the greatest common divisor. For this reason the subject will probably disappear from arithmetic in the next generation.

The corresponding expression in algebra is highest common factor. We cannot tell whether a given algebraic expression is greater than another unless we know the numerical value of the letters. For example,  $x^2$  is greater than  $x$  if the absolute value of  $x$  is greater than 1, even though its algebraic value may be less than 1, as in the case of  $x = -2$ . But  $x^2$  is less than  $x$ , if the absolute value of  $x$  is less than 1, as in the case of  $x = \frac{1}{2}$ . Hence the word "highest" is used instead of *greatest*, referring to the degree rather than the absolute value of the expression. The remarks already made concerning the greatest common divisor in arithmetic apply to quite an extent to the highest common factor in algebra. Although there is no algebraic decimal fraction to replace the common fraction, as there is in arithmetic, nevertheless the practical uses of the highest common factor were formerly much exaggerated. Hence the subject is at present given less attention than was formerly the case.

D. E. S.

**GREAVES, JAMES PIERREPONT** (1777–1842) — English Pestalozzian, acquired a competence as a merchant, but lost his property by French spoliation during the Napoleonic wars. Through his interest in philanthropic movements, he joined Pestalozzi (*q.v.*) at Yverdon in 1817 in order that he might familiarize himself with the best means of educational reform. A year later he took charge of the coeducational orphan school which the Swiss reformer had organized at Clendy, near Yverdon. Greaves returned to England in 1825.

and became secretary of the Infant School Society (*q v*) of London. At his request Pestalozzi wrote him a series of letters on the education of the child, which he translated and published in English (*Letters on the Early Education of the Child*, London, 1827). In 1832 he settled at Randwick, Gloucestershire, and engaged in a scheme for the improvement of agricultural laborers, similar to that which Pestalozzi had originated at Neuhof in 1769, and five years later he founded at Ham, near London, a Pestalozzian school, which he named Alcott House, in honor of A. Bronson Alcott (*q v*), the American Pestalozzian. He shared the transcendental views of the American philosopher and invited him to England. He founded the *Æsthetic Society* of England, and in various ways engaged in reform movements in education. W. S. M.

#### GREECE, EDUCATION IN ANCIENT —

The education of the Greeks was to a peculiar degree the embodiment of an attitude of life, the practical application of a theory of value which was taking shape from the age of Homer to that of Aristotle. It is proposed, first, to trace the growth of this theory of values to a theory of education, secondly, to sketch the views of education laid down by Plato and Aristotle, and then, with the Greek point of view thus determined in a measure, to describe Greek education in its actual working.

Stated briefly and generally, Greek education was based on certain essentially Hellenic characteristics that are at least as old as Homer and Hesiod, — a keen delight in physical strength, skill, and beauty, a belief in reverence, moderation, and social obligation or justice, and a feeling for form, not as form, but as expression. The delight in bodily beauty and effectiveness is sufficiently illustrated by the games at the funeral of Patroclus (*Iliad* XXIII), by the festivals — to name only the greatest — at Olympia, Delphi, Nemea, and the Isthmus (see the *Odes* of Pindar). The ideals of reverence, moderation, and justice, presented more or less dimly in Homer and set forth clearly in the *Works and Days* of Hesiod, are at the very basis of the Spartan system of education. The Greek emphasis on form as selective expression was not explicitly stated as a conscious attitude until the fourth century, yet it is inherent in every line of poetry chanted or sung from Homer to Sophocles, and in every vase painting from the geometric period to the fifth century.

Even in Homer there are signs of the coming

end of the extreme individualism — good in its fearless spontaneity, bad in its half savage indifference to law — which forbade any conscious effort to attain a real social ideal through education. Individualism is definitely limited by Hesiod to emulation. The *Works and Days* sets forth a clear social ideal based on justice and its corollary, moderation, or self-restraint. And the educational system traditionally ascribed to the Spartan Lysurgus (c. 800 B.C.), while unique in that it aimed at the perpetuation of the military supremacy of a conquering race, was in its most fundamental features a definite application of the principles set forth in Hesiod, — self-restraint, subordination of individual aims and desires to those of the social group, and an essentially moral training through precept, practice, example, and emulation. The wild freedom of Homer had given place to law. Individualism had given place to socialism. And to a greater or less degree this was increasingly characteristic of the whole movement of the Greek world from the ninth century to the fifth. But intense as the social feeling, the city patriotism, became in all of the Hellenic cities, it was usually less extreme than in Sparta, and was balanced both by a stronger individualism in political life and by a keen delight in such individual expression as was afforded by music, literature, which was hardly differentiated from music, and art. Gymnastics, while doubtless the object of special emphasis in the soldier state of Sparta, continued to be regarded with enthusiasm by Dorians and Ionians alike. Gymnastics and music were indeed the objects of a devotion never accorded to what we often regard as the typical Greek art of sculpture. Yet underlying all of these was the feeling expressed in the Delphic motto "Nothing in excess," the practical expression of that idealism which was the fundamental characteristic of the Greek attitude to life, the search for the essential in all things, the ruling out of everything irrelevant and inharmonious.

**Educational Theory** — Education in Sparta aimed simply at the development of soldier citizens, trained to the utmost physical effectiveness and to such moral and intellectual virtues as would make for the perpetuation of Sparta as a military power. This was attained by a varied and effective gymnastic training, games, and contests that tested endurance, judgment, self-control and resource, music that inspired to valor and constancy, grave discussions of moral issues, above all by a barrack life of strict discipline and division into companies captained by the older boys. Important as was the training of the body in the system of Lysurgus, it is a mistake to regard it as fundamental. The essential aim of Spartan education was moral. And so absolutely could the Spartans rely on the result of this training that they could even include the art of successful stealing in their curriculum, believing that

while the training in resourcefulness and judgment was a positive gain, any resultant disregard for the rights of others would be overwhelmingly outbalanced by the intensely moral and social character of the system as a whole.

So absolute a system of prescription, though admired by individual Athenians, like Plato and Xenophon, was quite alien to the free spirit of Athens. Their education was from the first a private affair, though custom prescribed a fairly uniform curriculum consisting of letters, music, and gymnastics, with a minimum of arithmetic, astronomy, and geometry. Athenian educational theory was formulated tentatively in the fifth century, definitely in the fourth; and as an interpretation of practice, an effort to give a rational account of existing facts in order to see the goal more clearly, it needs to be understood before the details of educational practice are approached. Not that we can separate theory and practice in any hard and fast way. The first definite statement of the aims and methods of Athenian education is indeed a description of practice, and is only theory in so far as it is an attempt to view the situation as a whole in relation to an ultimate aim. This is the description which Plato puts in the mouth of Protagoras as part of his argument for the possibility of moral education. "Education commences in the first years of childhood, and lasts to the very end of life. Mother and nurse and father and slave-tutor (pedagogue) are quarreling over the improvement of the child as soon as he can understand them, at every turn they expound to him that this is just and that is unjust, this honourable and that the reverse, this holy and that impious, and generally, do this and avoid that. And if he obeys, well and good, if not, he is straightened out with threats and blows, like a piece of warped wood. At a later stage, they send him to teachers and enjoin them to see that his manners are good, even more than his reading and music, and the teachers do their best. And then, when he can read, they give him the works of great poets which he reads at school, where he finds many tales and admonitions, and praises of ancient famous men, which he learns by heart in order that he may desire and emulate them. Then again the teachers of the lyre take care that he does not fall into mischief, and introduce him to the poems of other excellent poets, who are the lyric poets, these are set to music, and their tunes and rhythms made familiar to children, in order that they may be more gentle, and harmonious and rhythmical, and so better fitted for speech and action, for the life of man in every part has need of music and rhythm. Then they send him to the master of gymnastics, to fit him for war. This is what is done by the richer or higher classes whose education lasts far longer than that of the rest. Lastly, when they are grown up, the

State compels them to learn the laws, and live according to them" (*Prot* 325-326).

The supreme interpretation of Athenian education was that of Plato himself. The system of education described in the *Republic* is devised only for rulers, and for rulers of an ideal, not an actual, state. But the curriculum is not essentially different from that which regularly prevailed in Athens, and the whole system, theoretical in that it endeavors to determine a rational ideal and a rational method, is practical in that it is soundly based on existing practice. Plato's conception of the aim of education is stated in the seventh book of the *Republic*. In the famous parable of the Cave he shows men living in darkness, seeing only shadows on the wall before them, and taking these shadows for realities. Let one of these cavemen be brought suddenly to the light of day and he is dazzled, blinded, thankful if he can escape to the Cave once more from the light which to him is darkness. But let him be taken more gradually to the outer world, and his eye will gain power to see, and the real world will at last dawn upon him in its infinite grandeur. Here, then, is the function of education, — to turn the eye of the soul to the light in order that it may see and love truth (*Republic*, 518). The sun in the physical world is the type of that fundamental reality which makes everything else intelligible, and knowledge of this fundamental reality — called by Plato the Idea or Form of Good — is of all things the most precious, the goal of every true student. For Plato's Idea is simply the essential, — what is meant when we use the words law, principle, essence, that is, everything which makes it intelligible. He applies to education that which is the keynote of Greek thought and Greek art, — insistence on the fundamental, the universal, and indifference to the accidental, the narrowly individual.

Plato's system of education represents an effort to attain this ideal — the understanding and adoption in life of those things that are fundamentally true and therefore of fundamental value. His general treatment rests on two fundamental presuppositions. (1) that education is of fundamental importance to the State (*Republic*, 425. "The bent given by education will determine all that follows") and should therefore be required and controlled by the State, (2) that man is an organism, i.e. that he is endowed by nature with certain powers which will develop, if the proper conditions are given, and that the teacher's profession is not unlike that of the gardener. These two premises being assumed, Plato outlines a system of training for the young that will stimulate love for what is good and beautiful, dislike of what is bad and ugly, and right action that will become so natural, habitual, and pleasant as harmonious sound is to a musician. This is done through careful

choice of literature, both as regards subject matter and form, careful instruction in music, peculiarly important because of the subtly powerful influence of rhythm and harmony on the human soul, and the equally careful effort to have every detail in the child's environment healthy, elevating, and harmonious. To create the right standard of truth and beauty at the outset, before the child is in any way conscious of what is being done, is to make wrong action as repulsive to him as a discordant crash of sounds, and to turn his mind away from the false, the petty, the fleeting, and insignificant as certainly as his eye would turn from the canker worm to the perfect blossom, from the frame to the picture. That a perfect result will follow in every case from even the most wisely devised system of education Plato by no means takes for granted. The imperfect seed will not grow into a perfect flower, and besides, different natures will respond differently and perhaps unexpectedly to similar treatment. There must, therefore, be tests, "labors, vexations, and contests," accompanied by vigilant observation of conduct. Education will thus have its selective side, and only those fitted for it will go on to what we might call the secondary and advanced stages of the course.

For it is necessary that as the child's mind expands and grows in power he should learn to examine his standards and methods of thought for himself. "When reason comes, he will welcome her most cordially who can recognize her by the instinct of relationship, and because he has been (wisely) nurtured", but it is none the less true that reason must come, and that the growing mind must learn to examine standards, to search consciously for principles, to abstract, question, and generalize. With this in view Plato would introduce his pupils to arithmetic, where they will grow accustomed to the easiest of all abstractions, that of number, to geometry and its problems of space, to astronomy and the laws of rhythm and harmony that control the heavenly bodies. This course of science will lead to philosophy, the study of fundamental truth. And when the student has at last learned to look on beauty and truth in their essential reality, he must turn back to the weary and troublesome problems of actual life in society to serve his fellows as a leader and teacher. His education leads, not to the barren and empty speculation associated with the word "philosophy" by superficial men of the world. Rather are his philosophers wise leaders of men who have learned to see things as they are, to understand and unerringly seize upon the true and the beautiful.

The value of all this is not simply the value of a poetic philosopher's dream. It is rather the interpretation of the essential spirit of Greek education by the greatest of all Greek thinkers. It was practically adopted in its

main features by Aristotle (*q v*), fragmentary as is the treatment of education by Aristotle that remains to us in the *Ethics* and the *Politics*. Aristotle, like Plato, urges that education should be compulsory and controlled by the State. He does indeed insist on defining the Form of Good as the highest good for man. Happiness, and happiness as the perfect exercise of the rational activity which is man's unique characteristic, so that education becomes in its highest aspect a training for leisure, for the contemplative life. And he gives a new clearness to two points that seemed to him to need special emphasis, — the significance of habit and the doctrine of the Mean. But Aristotle's value here as elsewhere is rather in a certain formulation and clarifying of the issues, a practical insistence on accurate definitions, than in any real modification of his master's teaching. In his statement of the aim and method of education, of the curriculum, of the ethical purpose of education and its relation to the state, Aristotle leaves Plato's doctrine untouched. So that we may safely say that the system outlined in the *Republic* remains for us the final statement of the theory of Greek education, the one perfect interpretation of its letter and its spirit. C F L

**Educational Practice** — The first thing to be noticed about the Greek infant was that its father had powers over it wholly denied to modern parents. The first question after its birth was this, Would the father rear it or expose it? Greek literature has so many allusions to the exposing of infants, that it must actually have occurred in Greek experience. But the frequency of this *motif* in the New Comedy is hardly good evidence that such barbarity was of everyday occurrence. The fact that there is no evidence of a distinguished person in all Greek history, who had been picked up and reared as an exposed or deserted child, may be taken as proof that in the case of male infants exposure was very rare, unless the child showed congenital deformity. Regarding females, the case is different. Indeed, the great majority of the instances met in the comedies of exposed children, afterwards recognized, are those of girls. Plato sanctions infanticide under certain circumstances, and this is even worse than the exposing in some place where the child would probably be picked up as a slave. It is not unlikely that one of the causes of the dwindling away of the Greek population by a strange atrophy in the third century B.C. is partly due to the exposure of female children by selfish and barbarous parents. In the many suits of the Attic orators about family affairs there does not seem to be a case in which a large family of children is concerned.

When the child was once accepted by the father, there is every reason to believe that it was treated with every kindness, nay even with luxury and indulgence. The well-known pas-

sages in Homer about Hector's child Astyanax, both during his prosperity and when left to a widowed mother, and other casual references, not only in Homer, but in Herodotus and in the lyric poetry, show clearly enough that babies were as much prized and as much attended to as in modern life.

The string of infantile diseases, which are the bane of modern life, are not heard of. Not even in Hippocrates' admirable clinical observations do we have croup or teething or measles or whooping cough. Malaria there probably was, and there is even evidence that it contributed not a little to the further decay of the population, where marshy lands ceased to be continuously cultivated. Fashionable people kept nurses, and it was a matter of high fashion among Athenian and other aristocrats to have a Spartan woman for the purpose, as she was supposed to know better than others how to make the child healthy and strong in limb. But only some misfortune, such as a successful raid, could reduce a genuine Spartan to such a condition. Probably women from the Lacedæmonian coast, although Helot women, were so called when they were fortunately obtained. What the usual diet of infants was we are not told except in Homer, who says Astyanax was fed upon marrow and mutton suet. This seems part of the general meat diet in which the heroes indulged, and which was certainly widely different from historic Greek diet. In the latter very little meat was eaten by anybody, and only on special occasions, such as feasts to the Gods. Contrary to the modern practice of hiring foreign nurses or governesses to teach the child some European tongue other than his own, when he can acquire it without the trouble of grammar, — this side of education did not exist among the Greeks, who despised all tongues but their own. For any child to be brought up speaking even Egyptian or Macedonian would have been thought a blemish rather than an accomplishment. But beyond this negative certainty, the women's apartments, in which the children, both boys and girls, were kept for the first few years, are closed so completely to us that but few things about the life of Greek babies can even be conjectured. A few late epigrams tell of the grief of parents bereaved of their infants. The backwardness in culture of Greek women leads us to suspect that babies were more often badly brought up and overindulged than at present, even though the "Spartan mother" is still proverbial and shows that a lofty ideal was not unknown to them. But in the rest of Greece it may be assumed that the young child arrived at his schoolboy age more willful and headstrong than most of our watched and worried infants. Archytas, the philosopher, earned special credit for inventing the rattle, and so saving much damage to household furniture by occupying children with this toy.

It must be remembered that the external cir-

cumstances of a Greek boy's life were somewhat different from the present. Except in some few places, such as Elis, and partially at Sparta, which consisted of five villages, all old Greek life of the better classes was town life, so naturally Greek schools were day schools from which the children returned after lessons to the care of their parents. To hand over boys, far less girls, for pay to the charge of a boarding school was unknown, and any such proposal would doubtless have been severely censured. Orphans were placed under the care of their nearest male relative, even when their education was provided by the State. Again, as regards the age of beginning school, it will naturally be earlier than is usual among us, for day schools can receive very young children, and in but few households were either father or mother able or inclined to undertake the training of their children in school work. Even the knowledge of letters and reading were obtained from the schoolmaster. But the small number of subjects taught prevented any hurry such as that in modern times, when there is no adequate time for languages, sciences, histories, and all the rest which is crammed into our unfortunate children. Above all, there were no competitive examinations save in athletics and music. The Greeks never thought of promoting a man for dead knowledge, but for his living grasp of science or life. Owing to these causes, the theorists discussed the expediency of waiting till the age of seven before beginning serious education. Some there were who recommended easy and sportive lessons from even an earlier age. On this point, therefore, they agreed fairly well with modern views. But Greek parents were, like those of the present, often over-anxious or nervous or dilatory, and it is clear that there were intervals between infancy and school life which were spent in playing in the street and doing mischief. Even so aristocratic a boy as Alcibiades is reported by Plutarch to have shown his pluck and obstinacy by lying down in the highway, when a coming cart threatened to disturb his game, and daring the carter to drive over him. There is, also, extant a long list of names for the games of boys preserved in glossaries. It belongs to the question of education to know something of the nature of these games, wholly different from the exercises and competitions afterwards carried out in the palæstra. Among young boys, as among the lower animals, most games in concert are imitations either of war or the chase; the rest are the practice of some bodily dexterity, such as hopping, or throwing, or whipping a top or shooting with marbles. All these were common in Greece. They had the hobby horse, also the hopping on a skin bottle filled and greased, and blindman's buff, etc. There was a game like our peg-top spinning and contests of two sides or teams of boys. There is no need to enumerate all these particularly. More peculiar were the game of throw-

The Pankration, and a Paidotribe.

Wrestlers, Paidotribe, and boy preparing the Ground for Jumping.

# A GREEK GYMNASTIC SCHOOL.

From a Kalyx

ing up five pebbles or knucklebones, and receiving them on the back of the hand so as to lie there. Another game consisted of flying a beetle with a long thread, and fastening to him a lighted wax splinter (or match). This barbarous amusement is said to have been still in use recently in modern Greece. Spinning tops, rolling hoops, and playing with balls were all common. This latter was done even by grown girls, according to Homer's *Odyssey*. Some of them approach both to our football, handball, and even lacrosse. The use of knucklebones or *astragal*, smoothed and squared so as to serve for dice, afforded scope for the children's gambling propensities, and throwing with them for luck is often represented in Greek art. We also have in the extant specimens some which were clearly loaded. Another common game was the Italian *morra*, the prompt guessing of the number of fingers thrown up by the adversary which can be seen every day in southern Europe. Very likely the game of *boechi*, which corresponds to our bowls, and is so universal in Italy, has an old Greek origin. Walking on stilts, leap-frog, swinging, and tossing in a blanket will suffice for any further enumeration, which serves only to show how remarkably modern were Greek, or perhaps how remarkably primitive is our catalogue of little boys' games.

Nothing is known about the condition of little girls, except that they certainly engaged in ball playing. As among us, so of course in Greece, girls joined in the games of their brothers, so far as they could be carried on indoors, or in the closed court of the house. There are graceful representations of them practicing swinging and seesaw. Dolls they had in plenty, and dollmaking (of clay) was quite an extended trade at Athens. In more than one instance there have been found in children's graves their favorite dolls laid beside them as eternal keepsakes. Most unfortunately there is hardly a word left of the nursery rhymes, and but little of the folklore, which are of considerable influence in the education of our children. The fables attributed to Æsop show how popular such literature was from an early epoch.

When we come to school life the most striking difference between the Greek education and ours is this, that even with little boys, physical development was attended to by a special master in a special place, except in those rare cases where they practiced out-of-door sports, and these cannot be commenced at the age of seven, or even near it. The Greeks indeed afforded their boys two contrasted sides of exercises — hunting, which was practiced by the Spartans, and also no doubt by the Eleans and Arcadians, as we may infer from Xenophon's *Tract on Hunting*, and gymnastics, which in the case of boys was carried on in the so-called *palaestra*, a sort of open-air gymnasium (in our sense) kept by a private individual as a speculation, to which the boys were sent, as to a schoolmas-

ter. The Spartans had ample scope for hunting in the glens and coverts of Mt. Taygetus, and hence they despised mere exercises of dexterity in the palaestra, just as modern sportsmen think very little of spending days in a gymnasium. As to open air games, like hockey, football, etc., they seem not at all so well provided, and though they could have practiced rowing to their hearts' content, free men seem only to have done it as a duty in naval war, at other times slaves and hirelings worked their ships. Herodotus speaks of the generality of sailors (and that included a large section of the citizens in war) as able to swim, but Greek literature is silent regarding any competitions in this accomplishment. But in another point the Greeks agreed with the modern English, they regarded sport as a really serious thing, and unless it is so regarded, it will never be brought to any rational perfection. But then the Greek did not, like all people imbued with Semitic religious ideas, regard religion with such great solemnity. Their religion was not more serious than their sports, nay they were often combined, "for the gods too love sport," says Plato in his *Cratylus*, a very significant and thoroughly Greek sentence. The greatest feasts of the gods, and the funerals of the greatest men, were glorified by intensifying human pleasures, by games, and theatrical and dancing exhibitions.

There is no evidence whether the boys went to their palaestra at the same age as to school, and at a different hour of the day, or at a different age, taking their physical and mental education separately. Nor is it known which came first. The Germans think the palaestra came first, but it seems far more natural that letters should be taught from the age of seven, and exercises of the body later on. Even the theoretical schemes of Plato and of Aristotle do not help us here, it is one of the many points which every one omits to mention because it was familiar to all. We shall here take the physical side first, for the mental side is prolonged into higher education. And here, too, dividing the exercises of the palaestra into wrestling and dancing, more properly exercises of strength and exercises of grace, athletics will be treated first.

In order to go safely from home and return again, Greek boys going to the palaestra were put under the charge of a pedagogue (boy-leader), not to be mistaken for a schoolmaster, though the authorized version of the Bible has done it, when it makes St. Paul say "The Law was our Schoolmaster to bring us unto Christ." The Greek pedagogue was merely an old and trusty slave, who was often fit for no manual labor. He was always ignorant, and never respected. He was in one sense, too, a chaperon, guarding his charges from making acquaintances or cultivating intimacies with other youths. The keeper of the school and trainer of the boys, though no state official,

was under very strict regulations at least if the quotations from such laws in Æschines' speech *Against Timarchus* are to be believed. But if there were such penal laws, there is reason to believe that except in the case of some grave scandal they remained a dead letter. Still at Sparta, even in the gymnasia for grown youths, the regulation *Strip or go* was enforced to prevent a crowd of idle loungers from collecting. There are many pictures on vases of the interior of a palæstra. A rude bust of the bearded Hermes, the patron god, indicates it with certainty. A middle-aged man with a wand in his hand is directing the exercises, often wrestling, of the boys. We know from the *pentathlon* at Olympia for men, and even for a while for boys, that its five exercises—running, leaping, throwing the dart, throwing the discus, and wrestling—were the usual program. For older youths, boxing and the *pancratium* were added, save in Sparta, where such violent contests were thought to lead to disfigurements, and at all events to private feuds. The higher exercises were undertaken after rubbing the skin with olive oil, which became quite a heavy expense to some Greek cities, and was sometimes provided by private benefactions. When the exercise was over, the oil and dirt were scraped off with a *strigil*, as may be seen in the splendid statue in the Vatican of an athlete so cleaning his arm. The luxury of a bath is not mentioned, for in most Greek towns water was very scarce, and the nation was not given to much washing. The few details which remain about training, in the stricter sense, show that the Greeks were not scientific in their notions. Either cheese or in later days quantities of meat were specially recommended and the athletes were in consequence heavy and stupid people.

We have already quoted the passage from Plato's *Protagoras* in which the ordinary education of the Athenian is described. There is another passage in Aristophanes' *Clouds* (961 *et seq.*) which describes the older strict discipline of Attic boys, who were not allowed to whisper before their elders, who went in troops to school even in the winter mornings in deep snow, clad in a single tunic, and were kept at work by the master learning old traditional hymns—all this in contrast to the inroads of luxury and laziness, of vulgar and florid music, which that strict conservative reviles just as our old-fashioned people are shocked with modern education for girls. Both passages speak the voice of a cultivated society, and of high moral principle, which makes them worthy of the best modern and even Christian education. But the far wider connotation of the word "musical" is at once noted, which included a knowledge of good poetry, and also of the elegant and rhythmical dancing which was part of the solemn service of the gods. It included, in fact, every graceful, æsthetical, and intellectual accomplishment.

From these and many other passages it appears that the Greeks administered their early moral education just as the Protestants of England and America, through a book regarded as inspired; just as the stories of the Old Testament, as well as the teachings of the New, were taken as the highest moral teaching (not without wonderful liberties of interpretation, though the text was sacrosanct), so the Greeks treated Homer as their Bible, containing all the morals a child should know. Regarding the punishments which they inflicted, the notions then and now, or at least fifty years ago, are about the same. All the Greeks acknowledge the justice and expediency of corporal punishment, and only caution parents against applying servile punishments to free boys. A fresco from Pompeii shows a boy hoisted on the shoulders of another, being flogged by the master. At no time was the teacher of young boys for pay ever highly esteemed. There was, as already mentioned, no qualification demanded by the State. It must often have been the recourse of penniless or broken down men, just as in modern times penniless girls of the better class used to turn governesses. Hence the sneer of a comic poet: "The man is either dead, or teaching the alphabet."

The school was generally called *didascalæon* (teaching place) to distinguish it from the palæstra. Every Greek town had one or more, some of them large, for Herodotus tells of one at Chios, where the roof fell in, and killed 119 out of the 120 children attending it. In villages there were poor appointments, and such a school in Greece corresponded to the Irish hedge school or the cloister school of old monasteries. Statues of tutelary gods and some simple ornaments were found in the better ones. The master occupied a high seat, above his classes, the main difference from our arrangement was the absence of tables or desks, it being the universal custom when reading or writing to hold the book or roll on the knee. On the walls hang various things, all of which are not now understood, but among them were implements for reading and writing, boxes for book rolls, reckoning boards with pebbles strung in them, flute cases, and lyres. Lucian, a very late authority, says there were even notice boards, which were white, covered with chalk. Hence writing with the finger would be quite legible, especially if the original ground was black. There are also traces of pictorial illustrations of scenes from the *Iliad*, preserved at the Capitoline Museum in Rome, which seem to have been hung up in schools, like the zoological and other sheets in modern schools. Though later theorists speak of the necessity of pauses and variations in study, periods of holidays for all, such as the dog days were at Rome, are not referred to. As every child was taught to read and to recite from the great poets, a double object was attained. The school-

boy was taught to speak accurately and read rhythmically, he was also made acquainted with the choicest passages in older literature. Written books not being as common as they are now, much more was done by dictation and conversation.

When children came to writing, they used tablets covered with wax, on which the pointed stylus drew a sharp line, which could be smoothed out again with the flat reverse end. In writing on papyrus a reed and ink were used, and there are extant many boys' exercises on papyrus from Greek tombs in Egypt. The knowledge and study of grammar only came in with the Stoics and was the task of grown men, rather than of boys. There are many specimens of this sort of analysis in the Platonic literature, and indeed some very primitive ones in Aristophanes' *Clouds*. Geometry and arithmetic (the science of number) were also advanced studies, but the art of reckoning was learned like our practical use of figures. It is known that the system of notation learned was not the cumbrous one found in inscriptions but the very compendious and practical one used in countless Greek papyri found in Egypt. The alphabet enlarged by three signs for 6, 90, and 900 supplied the whole system. With  $\epsilon$  began the tens, with  $\kappa$  the twenties, with  $\rho$  the hundreds, with  $\chi$  the thousands.  $\text{M}$  was 10,000. Thus 10049 was  $\text{M}\mu\theta$ . There was no symbol for 0, but the place in the alphabet told at once what is now expressed by cipher following a number. Fractions were expressed by the same letters with an accent over them. Only the denominators were written, the only numerator being 1,  $\frac{2}{3}$  had a special sign, in other cases a fraction was broken up,  $\frac{1}{2}$  was expressed as  $\frac{1}{2}$ ,  $\frac{1}{3}$ ,  $\frac{1}{4}$ . Further details would be out of place here, but in these symbols are found very elaborate computations rising to very large figures.

Turning to what are now called accomplishments, but which the Greeks called music, there are a good many late and not very trustworthy authorities stating that drawing (not of landscape but of figures and of household objects) was generally taught. This seems very doubtful, but no one can deny that music (in our sense) was never omitted. The Greeks put the greatest stress on the directly moral and immoral effects of music, according to the scale or mode used. There were strict and sober kinds, there were effeminating and even lewd sorts, the proper educator should not allow the latter to be heard by boys. Our difficulty in appreciating this side of Greek education is that, though we know and can appreciate their simpler scales or modes and their notations, the fragments preserved of their tunes are so unlike anything now known and understood as music, that no modern composer, however learned, could supply a missing bar in the Hymn found at Delphi with even the smallest proof that his restoration was correct. In

society there were great gentlemen, like Cimon, who sang and accompanied themselves on the lyre. But in general, playing and singing in society was left to the not very reputable professional. Choral singing and dancing with accompaniment of lyre or flute was a splendid feature in Greek feasts and in the theater. These solemn dances and the singing were performed by lads whose voices must have been formed again after breaking, — a thing not noticed in the usual accounts which make them boys of fourteen to eighteen, when modern boys lose their voices. Of the instruments in use, the *symyx* or Pandean pipes were only used by shepherds, and not in schools. The *trigónon* or triangular harp, and the double flutes were only used by professionals. The lyre was made by stretching gut strings across the concave side of a tortoise shell, which is often found clean and dry in Greek watercourses. There were much more elaborate kinds which added a neck and made an instrument something like the modern guitar. The former had seven or ten strings. Their flutes (though they knew what we use) were rather clarionets held straight, and with a wide mouth.

The last stage of a boy's education was the so-called ephebic training, which was intended to prepare boys directly for the service of the state as soldiers, and in that respect is like the compulsory soldiering in nations that have a conscription for their defense. No boy was allowed to pass from his school days into citizen life without some training in the use of arms beyond that of the *palæstra*, and in military discipline. These ephebi had two duties to perform, the most important was patrol duty on the frontier of their state, where they did the work of military police, and probably also of preventing any considerable smuggling across the frontier so as to defraud the duty raised in the recognized markets where citizens from both states exposed their wares. They also stopped the depredations of footpads or highwaymen, so that brigandage was quite rare in the more civilized parts of Greece, till the days of its depopulation and decay. These youths were dressed in the short dark gray cloak and the soft hat seen in the Parthenon frieze, which also depicts the second great duty of the ephebi, that of adorning the feasts of the gods in solemn procession. All the varieties of their duty appear in this famous composition. They are carrying sacred vessels, leading victims, managing prancing steeds, with exquisite grace and in wonderful variety. It is remarkable that in spite of this clear exhibition of the class, it had not yet attained any state recognition, so far as can be inferred from Herodotus and Thucydides (fifth century B.C.). In later days, numerous inscriptions show that the ephebi, with clubs and meetings, with their resolutions and decrees, were at least as important as the societies of students in our modern universities. Stobæus has preserved a text of the oath by

which these youths were bound. It has been criticised and questioned by the skeptics, but even if somewhat modernized, perhaps in Roman days, it represents quite truly the spirit of the whole institution. "I will never disgrace these hallowed weapons, or abandon my comrade, beside whomsoever I am placed (in battle) but will fight for both sacred and secular things with my fellows. I will not leave my country less, but greater and better by sea and land. I will obey the rulers appointed and the established laws, and whatsoever new laws the state may lawfully establish, and if any one attempt to abolish the existing ordinances or disobey them, I will resist him, and defend them individually and with the rest. Be my witnesses Aglauros, Enyalios, Ares, Zeus, Thallo, Auxo, Hegemone." This list of gods can hardly be a late invention. It is not within the scope of this article to describe the exaggerated importance of this ephebic institution in Greece under the Roman Empire, when fashionable strangers crowded to Athens as their place of intellectual amusement as rich Americans now go to Oxford. It was then a genuine part of Greek education, much as it has been described by Aristophanes and Xenophon.

In higher education it is impossible to ignore the famous teaching of the sophists, who were not recognized or even approved by Greek politics, but who set up as adventurers, or itinerant teachers to train the richer and idle young men how to think and speak upon the subjects of the day. They desired to give by discussions and lectures not only a training in rhetoric, logic, and political sciences, but the gamut of information now offered by the leading articles of our daily press which profess to tell their readers what to think about the current topics of interest. Cultivated people can hardly appreciate how these superficial articles affect the thought of the lower middle and the lower classes in modern life. The sophists may have had this great influence on a small society, which had no books on daily topics and was more easily led by a persuasive teacher. Just as our newspapers contribute a great deal to general culture, so did the sophists. Just as they have grave faults, so had the sophists. But grave and perhaps just as are the charges of superficiality, irreverence, and destructive criticism made against them there must have been among them wise men and good teachers. Among the innumerable passages in Plato relating to the sophists we may note one in the *Protagoras* that is instructive and free from hostility. When Socrates asks Protagoras what he undertakes to teach he answers: "If Hippocrates comes to me he will not experience the sort of drudgery with which other sophists are in the habit of insulting their pupils, who, when they have just escaped from the arts, are taken and driven back into them by their teachers, and made to learn calculations and astronomy and geometry and music (he gave a

look at Hippias as he said this), no, if he comes to me, he will learn that which he comes to learn. And this is prudence in affairs private as well as public, he will learn to order his house in the best manner, and he will be able to speak and act for the best in the affairs of the State." "Do I understand you," I said; "and is your meaning that you teach the art of politics, and that you promise to make good citizens?" "That, Socrates, is exactly the profession which I make." But perhaps it was rhetoric, the art of persuasion and debate, that drew the youth of Athens to the sophists, rather than anything deserving the name of political science. Indeed, we may date from the age of the sophists the rise of rhetoric to the place that it was to hold in education through the entire period of Roman domination. (See ISOCRATES.)

If nothing has been said about the education of girls, it is only because nothing is known about it. Xenophon represents a bride coming into her husband's house, having lived her youth in darkness and in fear, knowing nothing but how to adorn her person and that artificially, with powder and rouge, and with enhancements of dress. The Spartan women brought up in great liberty, and freed from the strict discipline of the men, are spoken of now as specimens of bravery and patriotism, now as turbulent and mischievous to the peace and order of the state. But except that they trained openly like boys, we know nothing of their education.

The age of the Sophists, Socrates, Plato, and Aristotle, *i.e.* the later fifth century and the fourth, was the age of the breaking up of the older traditions and institutions, the collapse of the city state before the power of Macedon, and the scattering of the Hellenic culture through the eastern world by the conquests of Alexander. As was inevitable the old forms and standards of education, as of moral, intellectual, and political life gave place to a new cosmopolitanism and individualism. The dissolving and reconstructive effect of the new spirit was seen perhaps not so much in primary as in advanced education. Philosophy and rhetoric became immensely popular, and schools arose in Athens and Alexandria to which the previous century offers no parallel, such as the rhetorical school of Isocrates (393-338 B.C.) and the philosophical schools of Plato (the Academy), Aristotle (the Lyceum), and Zeno (the Stoa or Porch). In Athens the old custom of Ephebic education supervised by the State was joined to the three philosophical schools, teachers of rhetoric and logic were added, and thus was formed the University of Athens (*qv*). Athens had however one rival, especially during the earlier centuries of the Christian era, *viz.* Alexandria (*qv*), where another university grew up about the great library. But long before the suppression of the University of Athens by Justinian in 520 A.D. and the close of the intellectual greatness of Alexandria with the Saracen conquest (640 A.D.) Greek educa-

tion had begun to lose its distinctive characteristics under the influence of Roman rule and the rise of Christianity J P M.

#### GREECE, EDUCATION IN MODERN —

**Historical** — The history of education in Greece may be conveniently divided into four periods. The first of these extends from the sixth century B C to the third century of the Christian era, when Constantinople became the center of the Roman world. Although during this time the independence and unity of Greek national life was destroyed by the Macedonian conquest (338 B C) and finally by absorption in the Roman empire, Greek culture retained its distinctive character and was imparted to the conquering peoples. The second period coincides with that of Byzantine supremacy and ends with the fall of Constantinople in 1453. The third period is that of Turkish domination from 1453 to the War of Independence (1821), which ushered in the fourth or modern era. Of the earlier periods it is sufficient here to note that the first was that of classic Hellenism of which Athens was the proud center. The second period was marked by the fusion of Hellenic philosophy with Christian doctrine, and although during this time the ancient schools of Athens and of other Grecian cities declined, or were abolished by imperial decree, the Greek language and traditions survived in the brilliant capital of the East, for, while Latin was the official language of the Byzantine court, Greek was the language of the people, and Christian Hellenism the culture which drew scholars from the West to the University of Constantinople (See ALEXANDRIA, SCHOOL AND UNIVERSITY OF, ATHENS, UNIVERSITY OF).

The Turks, though not always openly hostile to Byzantine education and culture, looked upon it with indifference and contempt. They did not, however, interfere directly with the education of such Christian inhabitants of the Empire as could pay liberally for the privilege. Yet the Christians were not free men, no career, under ordinary circumstances, was open to Greek scholars save that which the Church

afforded, the common people were plunged in abject poverty, and the more fortunate hesitated to educate their children for fear of increasing their attractiveness. Girls were in danger of being appropriated for some harem, and every four years a certain number of small Christian boys were taken from their parents to be trained as janizaries. The very existence of this child tribute, and the tax of one tenth of the male children for employment in various offices, threw such gloom over family life that education could not well flourish, even if there were no other causes to prevent it.

Under these conditions the Greek church became the bond of union between all the Greeks in the Turkish empire, whether they lived in the Grecian peninsula, in the adjacent islands, or in Asia Minor, and the symbol of their lost national life. Such schools as they had were under the supervision of the clergy and often under their direct control. The schools for the common people were similar in many respects to the Church schools of Western Europe, but they resembled also in some particulars the ancient schools of Arabia and India. Pupils were taught to read the church service and the elements of arithmetic and writing. There were no special school buildings, but the pupils assembled in the narthex of some church, when their teacher was an ecclesiastic, or in the shop of some handicraftsman when he happened to be the school-teacher. They had no chairs, but sat crosslegged on mats or rugs laid on the floor. Their books were in manuscript, since the art of printing was not yet at their service. Each pupil usually had but one book at a time, and his promotion to another book was joyfully celebrated by his family and relatives. The schools were generally held in the daytime, but in the communities, where the pupils were engaged in labor during the day, night schools were sometimes held. A reference to these occasional night schools is contained in an old song which is still widely known throughout Greek lands.

In addition to the elementary schools, the ecclesiastical authorities established a higher order of schools termed Hellenic, their main purpose being to preserve the knowledge of rhetoric and the ancient language. The pupils of the Hellenic schools were generally intended for the service of the Church, although a small proportion looked forward to the secular callings. These two classes of schools, the elementary or demotic and the Hellenic, formed the basis of the national system established after the war of independence.

Even during the seven years' war (1821-1828) plans for an organized system of education were discussed, and in 1823, the Assembly of Atros voted that a system should be established. Foreigners devoted to the cause of the Greeks, in particular Lord Byron and

Leicester Stanhope, encouraged the effort. When temporary peace was secured and a provisional government established under Kapodistrias, the movement for a national system of education became general, and in 1828, within the short space of three months, twenty-two primary schools were opened in towns on the Aegean islands. In these the Lancasterian method of mutual instruction was used. The expense of the schools was borne by the communities. In January, 1829, Kapodistrias appointed a committee on elementary education, entrusted with the duty of organizing and establishing a system of elementary schools. This committee gave the elementary (demotic) schools the character which they still retain. Thus the foundations of the present system were laid before 1830 in which year the kingdom was organized under the protection of the three powers, Great Britain, France, and Russia. From time to time laws have been passed which taken together provide in detail for a system of public education.

**Present System — Administration** — The Minister of Education (and of Ecclesiastical Affairs) is one of the seven members of the cabinet. His appointment is largely a matter of politics and his tenure of office is usually brief. He has authority to determine what subjects are to be taught in all the schools, both public and private, and he fixes the time that must be devoted to each of these subjects in the course of study. In regard to the elementary and Hellenic schools he determines the minimum equipment for schools of each class and he appoints the committee that approves the textbooks submitted in the annual competition. The Minister appoints all teachers and has authority to move or remove teachers in the Hellenic schools and in the gymnasia. This power in the hands of a frequently changing ministry leads to insecure tenure, and it sometimes happens that teachers are changed from desirable to undesirable places for purely political reasons. He also appoints one chief inspector of elementary schools, four inspectors of intermediate schools, and one inspector of elementary schools for each of the twenty-six provinces.

At the head of each province is a Nomarch who is appointed by the King. As one of his duties consists in supervising the funds of the demes comprised in his province, it is not surprising that he is required to look after education. In practice, this official as well as the Demarch, confines his attention to the financial affairs of the schools and leaves the supervision of them and the examination of the pupils to a supervisory council which is composed of the bishop, the school inspector, the director of the gymnasium, or, if there be no gymnasium in the province, the director of the chief Hellenic school, and two other members, one of whom must be a professional man, and the other a business man. The inspector

visits the schools and reports to the supervising council, of which he is the chairman and executive officer. He is also a member of the General Council of Public Instruction. The Supervisory Council holds monthly meetings, transacts all business of the province connected with the administration of the schools, including the nomination of teachers, the discipline of pupils, the inspection of the equipment and instruction in the elementary schools of the province, and the examination of pupils.

The various demes (local districts) are required to establish elementary (demotic) schools, but a provision in the constitution makes it possible for the government to contribute to elementary education "in proportion to the necessities of the demes." Thus it happens that some of the schools in the poorer demes are entirely supported by the government, while other demes support their own schools. The total expense of conducting the elementary (demotic) schools for the school year 1907-1908 was 6,692,098 drachmas [\$1,231,574 91] (A drachma is equivalent to \$0 193.) The national budget for this year contained an item of 1,000,000 drachmas [\$193,000] for the purpose of assisting needy demes. More than 60 per cent of the elementary schools are supported wholly or in part by contributions from individuals or societies. Tuition in the elementary schools is gratuitous and the attendance for both boys and girls is compulsory from six to twelve.

**Elementary Education** — The elementary schools have either four or six-year courses. If the school provides a four-year course it is called a common (*κοινόν*) elementary school. If, however, it provides a six-year course, it is a complete elementary school. Of the 3418 elementary schools reported in 1908, 1571 were common schools, and 1847 were complete schools. In theory coeducation of the sexes does not exist in Greece, but in the smaller towns and in the rural sections, where the school attendance is not over seventy-five, both sexes attend the same school and are taught by one teacher. This arrangement is not permitted after the children are ten years of age.

In principle, Greek education is clerical, compulsory, and gratuitous. Thus three hours a week are devoted to the study of religion, which consists of instruction in sacred history, catechism, and reading from the Holy Scriptures. Jews and Roman Catholics have special instruction from the clergy of their own churches.

The teachers of the elementary schools are of three grades, depending upon their experience and preparation. The grade of the teacher determines not alone the type of school in which he may teach, but also the salary he is entitled to receive. Teachers of the third or lowest grade are usually found in schools where the enrollment is from fifteen to forty. If the enrollment is more than fifty-five a

first grade teacher is required. The minimum qualification for elementary teachers is a license from one of the teachers' training schools. The normal schools admit only men. Four of these schools have three-year courses, and one sub-normal school a one-year course. A school for training teachers of gymnastics was established in Athens in 1899.

TABLE I — THE SUBJECTS TAUGHT IN EACH GRADE OF THE SCHOOLS AND THE HOURS PER WEEK DEVOTED TO INSTRUCTION IN EACH SUBJECT

<sup>1</sup> The course of study for the complete elementary school includes the four years of the common school course and two years of the Hellenic school course.

The work of these schools is divided between theory and practice. Each of the normal schools has a practice school connected with it.

Men teachers of the first grade in the complete schools receive 1800 dr. per year, the second grade teachers receive 1440 dr., and the third grade 1200 dr. per year. Women of the same grades receive 1440 dr., 1320 dr., and 1200 dr., respectively. The local communities may increase these amounts. The teachers in the common schools receive 660 dr., 780 dr., or 900 dr. per year, depending upon the grade which they teach. Each teacher contributes to a pension fund. Tenure of office for these teachers is permanent during good behavior.

*Intermediate Education* — From the elementary schools boys may pass to the Hellenic schools. Those who come from the common schools enter the first year of the three-year course, but those who have taken the six-year course of the complete elementary school enter either the second or third year of the Hellenic school. A recent Minister of Education urged that the last year of the course in these schools should be added to the course of the gymnasium. This would abolish the Hellenic schools, for the first two years of their course is now given in the complete elementary schools. Of the 314 schools that were reported for 1907-1908, 267 had three classes, 15 had two second classes, while 32 had only a one-year course, 20,517 pu-

pils were enrolled in these schools, and the total expense was 2,477,022 dr. There usually are at least as many teachers as there are classes in the Hellenic school. Teachers in the Hellenic schools must have a diploma from the University, and to obtain the higher positions they must have passed the examination for the master's degree or even the doctorate. The head teacher, or director, of a Hellenic school is called the scholar, and receives from 2400 dr. to 3000 dr. per year. The salaries of subordinate teachers vary from 1200 dr. to 3000 dr. per year. These teachers are appointed by the Minister of Education and they have no fixed tenure.

*Secondary Education* — After independence was achieved, secondary education showed plainly the influence of German models. The first gymnasium in Greece was the Central School, founded in Ægina on the 13th of November, 1829. The number gradually increased, and at present there is a gymnasium in every town of sufficient size to justify the expense. In the larger cities, Athens, Patras, etc., there are more than one, according to the population. Each gymnasium is managed by its own faculty. At the head of the faculty is the gymnasiarch, who is both a teacher and general director. He also serves as one of the members of the Supervising Council for the province. The program of studies is regulated by an official scheme which is modified to suit the individual schools (see Table I).

The gymnasia are generally supported by the State, but in places where the population is not large enough to justify this expenditure by the State, the people of the community sometimes support one for themselves, paying the expense in some ingenious way. For instance, the town of Nesson, in Messenia, not being favored by the government with a gymnasium, its inhabitants were in the year 1896 supporting one by a voluntary tax, levied and collected by themselves, of one centime on each oke of grapes or figs produced in their fields. Pupils are required to pay small entrance and certificate fees. The gymnasia are classical schools, but the physical sciences are included in their course of study. Until recently, however, the latter subjects have been little regarded, since the great importance of classic education in Greece overshadows the high claim that the physical sciences have on modern education. The schools lack apparatus, yet, improvement in this respect is taking place and professors are being secured who have won their diplomas in the physical sciences, and are, therefore, both capable teachers and interested in the progress of their specialty.

The younger Greeks are eager for education, and efforts are made to encourage this ambition. There is, however, a growing conviction that the education afforded by the schools is not sufficiently practical. Plans for modify-

ing the system have been considered by two recent national assemblies, but as yet no agreement has been reached. The experiment of a "practical gymnasium" is being tried now in Athens. No new gymnasium of the regular type has been founded since 1900, but between 1901 and 1908 six commercial schools, with four-year courses were established. In 1908 these schools were employing 33 teachers, and had 315 students enrolled. The total annual expense of conducting them was 113,640 dr.

TABLE II — STATISTICS OF THE PUBLIC SCHOOL SYSTEM FOR 1907-1908

	ELEMENT- ARY (deme)	HELLENIC	GYMNASIA	
			Public	Private
Schools	3,418 <sup>1</sup>	314	26	11
Teachers	4,336	931	183	97
Gymnastic teachers		9	26	6
Students				
Boys	170,374	20,517	3,941	1,352
Girls	71,059			
Total expense				
Drachmas	6,690,098	2,477,022	767,376	259,090
Dollars	\$1,291,575	\$478,065	\$178,065	\$50,161
Expense per pupil	\$5.35	\$23.30	\$37.58	\$37.92

<sup>1</sup> The 3418 elementary schools include 1571 common schools, 1224 complete schools for boys, and 623 complete schools for girls. The total also includes 2123 schools that are not supported by the State or demes.

*Girls, Education of* — The education of girls in Greece, beyond the six years of the complete elementary course, is a matter of private enterprise, the oldest school for girls having been founded in 1831 by an American missionary, Dr. Hill, and his wife. Lately, however, the faculties of the national university have been opened to women. Among the schools for girls the most important is the Arsakion. This school was founded in July, 1836, by the Society of the Promoters of Education, and named after its chief benefactor, Apostolos Arsakes. There are now several branches located in different cities. The course of study begins with the kindergarten and ends with a three-year teacher's training course. Certificates from this school qualify their holders to teach in the elementary schools. More than 1800 girls are enrolled in the school, and more than 800 were taking the teacher's training course in 1908.

There are numerous societies which maintain private schools, noteworthy among these being the Parnassos Society, which conducts a night school for poor boys, of whom more than 2000 attend.

*Higher Education* — The Greek educational system culminates in the National University at Athens. In April, 1837, Otto, who, after the death of Kapodistrias, had been appointed by the powers to be the first king of regenerated Greece, issued a decree for the establishment of a university. Following the custom of the Germans, he named the new institution after

himself, and not until 1862 was the name changed to National University. According to the decree of 1837 there were to be four faculties: theology, law, medicine, and philosophy. The latter consisted of two distinct sections, philosophy and science. In 1904 each of these sections was made a separate faculty. The faculty of theology is composed of six professors and four assistants. In the law faculty there are nine professors and nineteen assistants. The medical faculty which is the largest, has eighteen professors and forty-eight assistants. The philosophical faculty has twelve professors and five assistants, and the physical and mathematical faculty has twelve professors and eight assistants. In 1842 a seminar in Greek philology was founded in the faculty of philosophy. The peculiar function of this seminar has been the training of teachers for secondary schools. Other seminars and various laboratories, museums, and clinics are supported by the university. Among the other more important subsidiary institutions may be mentioned the national observatory built in 1846, the botanical gardens and museum, the university library with more than 300,000 volumes, and the national museum.

Three months before the close of the school year the combined faculties choose one of their number whom the Minister of Education appoints as rector for the next school year. The rector is the executive head of the university and its representative at all functions. In like manner each faculty chooses one of its members who is made dean of that faculty for the following year by the Minister of Education. The dean presides at meetings of the faculty, he arranges the program of studies, and represents his faculty in the university senate.

The financial administration of the university rests with the university senate, a body composed of the rector of the university, the dean, and one other representative from each of the faculties, except the faculties of philosophy and physical and mathematical sciences. Each faculty proposes the candidates for the professorships, and the Minister of Education appoints. Prior to 1882 the professors were named by the king. The government pays the larger portion of the salaries of the university officers. For the school year 1907-1908 the receipts of the university were 546,185 dr. and the expenditures were 507,349 dr. In addition to this the government paid salaries of professors and various other expenses amounting to 584,960 dr. This amount included 85,920 dr. to aid needy students and those studying abroad.

Students pay 2 dr. a year for a certificate of attendance in each course they take. Tuition amounts to 160 dr. per year, and there is an examination fee of 250 dr. in the legal and medical faculties, but only 150 dr. in the other

faculties. The diploma costs 50 dr. Students who have been graduated from the gymnasium, or institutions of like grade, are admitted without examination. The enrollment in the winter semester of 1909-1910 was about 2800 and in the summer session about 2500.

Other educational agencies which are not controlled by the government, but are sufficiently important to merit a mention in any description of the Greek educational system are the various archæological schools (see *ARCHAEOLOGY*). The oldest of these schools was established in 1846 and is called *École Française d'Athènes*. The American School of Classical Studies was founded in 1882 and is maintained by 26 American universities and colleges. The British School at Athens was founded in 1886. Other institutions are *Kaiserliches Deutsches Archæologisches Institut*, and *Italiensches Archæologisches Institut*. Greece maintains no archæological school, but two societies are active in archæological investigations. They are the Archæological Society, founded in 1837, and the Historical and Ethnological Society, founded in 1882.

**GREEK, STUDY OF.** — In *Universities and Schools of Europe* — Each successive migration of the Greeks may be said to have resulted in a twofold conquest, — a conquest by the invaders of the land and its inhabitants, and a more gradual conquest by the language which they spoke over the native tongue of the people whom they subdued. This widespread diffusion of the Greek tongue gradually, though slowly, resulted in a corresponding diffusion of Greek thought. And so there arose centers for Greek study in different parts of the Mediterranean countries, with Athens for a long time as the chief seat. The career of Athens, Alexandria, and Antioch as later centers of Greek learning is treated in outline in the articles on the universities and schools of those places. The condition of the study of Greek and the attitude of the Christian leaders toward Greek culture are also considered

under the topics *CHRISTIAN EDUCATION IN THE EARLY CHURCH*, and *CHURCH SCHOOLS*, and the various articles on the Church Fathers (see *AMBROSE*, *AUGUSTINE*, *BASIL*, *CHRYSOSTOM*, etc.) treat of the attitude of the early Church to Greek culture and the Greek language. The fusion of Greek culture with Roman is treated in the discussion of *ROMAN EDUCATION* (*qv*), and the conditions during the Middle Ages are presented in outline in the articles on education in that period. A brief sketch of the condition of the knowledge of Greek from the late Roman period to the Renaissance is desirable as an introduction to the consideration of the place of Greek in modern education (see also *RENAISSANCE, EDUCATION IN*).

Under Constantine the Great Greek became the language, first of his court, and then of the official world. When, in 340, his eldest son and successor in the Western prefecture, Constantine II, fell in a campaign in Provence, a Greek monody, recited at Arles, was deemed the most appropriate tribute to his memory. At this time, indeed, the churches of Western Christendom were virtually Greek colonies, and both the Scriptures and the liturgies which they used were in the Greek language, so that, as late as the sixth century, we find Casarius, the eminent Bishop of Arles, granting permission for the use of such versions, as an alternative to Latin, throughout the churches of his diocese. A like permission was accorded to the churches in Marseilles, and the numerous Greek words which found their way into the French or Romance language of this period afford like evidence. The imperial designs, however, were far from commanding general assent, and in Africa Tertullian (*qv*) had long before declared that there could be nothing in common between the "Academy" and the Church, while he openly denounced philosophy as "the source of all the heresies" (*De Præscript*, c. 7). Lactantius (*qv*), summoned by Diocletian to fill the chair of Latin at Nicomedia (then a famous center of Greek culture), found his position untenable, and at the court of Constantine at Gaul became conspicuous by the vehemence with which he inveighed against all Greek philosophy. His *Institutions*, which long held its ground in the Latin Church as the best authoritative exposition both of elementary Christian doctrine and the principles of Christian education, and the *De Nuptis* of Martianus Capella (*qv*), embodying the classification of the liberal arts sanctioned by the authority of Augustine (*qv*), and reproduced long after in the universities of Europe, alike mark the trend of education in the West in comparative isolation from Greek and from Hellenic influences.

Throughout the fourth century, however, Alexandria maintained its reputation as "the last great nursery of Greek culture," and in conjunction with a new school of theology could point to a succession of eminent divines

whose influence outshone, for a time, even that of Jerome and Augustine. Of this the mere citation of the name of Athanasius, Eusebius, Basil the Great, and Gregory Nazianzen (*qqv*) affords sufficient evidence; while John Chrysostom (*qv*), who was of Antioch, and subsequently Patriarch of Constantinople, has been designated "the model of a preacher for a great capital" (Milman, Vol III, p 118). He bequeathed to posterity a vast collection of sermons, letters, and treatises, of which the first-named have probably attracted in modern times a larger number of readers than the declamations of any other Greek orator, excepting only Demosthenes. In Byzantium itself the work of education went steadily on, and we have sufficient evidence that in the latter part of the eighth century there was ample provision for instruction in grammar, language, science, and philosophy (Bury, *Later Roman Empire*, Vol II, p 435); and the statement of Theophanes that Leo the Isaurian (680-741) put an end to "pious education" by shutting up the schools, refers probably only to a kind of theological seminary in the capital, which, under the management of its twelve teachers, became a nursery of superstition and was finally swept away in the commotion occasioned by the iconoclastic movement. It is certain that Europe was indebted to John of Damascus (nearly the last of the Fathers of the Eastern Church) for the introduction of the study of Aristotle into Christian education. Of the vast literature bequeathed by these Byzantine writers, although their pages contain many facts useful to the modern historian, comparatively few have been much studied in the universities. But the early years of the seventeenth century found Sir Henry Savile busied with his fine edition of John Chrysostom, just as those of the sixteenth century saw Bentley engaged on the restoration of the text of Origen.

In the Western Empire, down to the time of the Renaissance, Greek learning appears only in occasional gleams, and no continuous tradition is discernible. It was undoubtedly the design of Charles the Great (see CHARLEMAGNE AND EDUCATION) and his adviser Alcuin (*qv*) that the language should be taught in the schools created by their joint efforts, but there is no evidence that their instructions were carried into effect, although when John Scotus Eriugena (*qv*), a fugitive from Ireland, succeeded to the mastership of the Palace School in the time of Charles the Bald, something must have been heard at Aachen about both Martianus Capella and Origen. Otto III, himself the son of a Greek mother, was able to raise his preceptor Gerbert (*qv*) to the papal chair, and the latter understood Greek, while his pupil emulated the ceremonial and usages of the Byzantine court. But the prevailing tendencies in Rome, both then and long afterwards, were unfavorable to learning in any

shape, and in the thirteenth century a knowledge of Greek was even studiously disclaimed as likely to bring the possessor under the suspicion of heresy (Sandys, Vol. I, p 583). Greek thought and Greek science, however, often found their way where the language itself was unknown, and authors who had written on philosophy, mathematics, astronomy, and medicine were widely read in Latin translations, the professors at the newly founded universities, Salerno, Bologna, Reggio, Modena, Vicenza, Padua, and Paris being wont to dictate and comment on these versions, long prior to the fourteenth century. The Saracens, again, during the reign of the Abbasside dynasty at Bagdad (750-1258), and that of the Ommiades at Cordova (756-1031), became acquainted, through translations made by Syrian Christians, with Aristotle, Hippocrates, Galen, Dioscorides, Euclid, Archimedes, and Ptolemy, and conceived an ardent admiration for most of these writers, at the time when the greatest part of Latin Christendom, absorbed in an exclusive devotion to the *Organum* of Aristotle and an unquestioning acceptance of the doctrine of predestination as proclaimed by Augustine, looked distrustfully alike on the theology and the science of the East. In the year 1311, however, the Council of Vienne having decreed that chairs of Greek, Hebrew, Chaldean, and Arabic should be founded in the universities of Paris, Oxford, Bologna, and Salamanca, Clement V did not deem it prudent to withhold his assent. But here again the scheme proved abortive and the papal signature was expunged, while in the fifteenth century the commentators on the Clementines even venture to deny that it had ever been attached (Mullinger, *Univ. of Camb.*, Vol I, pp 482-483).

Such were the conditions under which Petrarch (*qv*), when he first visited Rome in 1336, could find no one to teach him Greek, and even in 1360 could name only ten scholars in all Italy who possessed a competent knowledge of the language, — "three or four in Florence, one in Bologna, two in Verona, one in Sulmona, one in Mantua, but not one in Rome" (Voigt, Vol II, p 107). The humanist, however, could not long rest content with that Latin literature which itself continually revealed its own indebtedness to the inspiration derived from ancient Hellas, and as the aid of competent instructors in Greek literature became more and more indispensable, Manuel Chrysoloras (*qv*), the representative of the imperial court at Constantinople in Venice, was invited to Florence, where his school, probably the earliest for Greek after that of Lorenzo Pilatus (1360-1363), was open to all comers. He himself received a salary of 100 gulden, and lectured in Latin (1396-1400), taking Plato's *Republic* for his first subject. Chrysoloras subsequently lectured at Florence, Pavia, Venice, Bologna, and Rome, he died in 1415, when on a visit to the imperial court at Con-

stance, whither he had repaired in order to take part in the proceedings of the great council. Under such auspices Greek now became fashionable in Italy, and it was rendered still more so by the genius of Guarino (*qv*), one of the disciples of Chrysoloras, who was able both to disarm the jealousy of Rome and to command the admiration of every scholar. In his classroom at Ferrara Englishmen were to be seen, some of them of distinguished rank, and when, in 1438-1439, the œcumenical council was convened in that city, his linguistic attainments were displayed in the skill with which he acted as interpreter between the deputies of the Greek and the Latin churches. (See also GUARINO, BATTISTA.)

The first great school for youth, however, was that of Vittorino da Feltre at Mantua, — the "Pleasant House," as it was termed. Although, after the fall of Constantinople (1453), the number of teachers in Italy was materially increased, they themselves brought but few manuscripts with them, and the paucity of the latter continued to be a serious hindrance to the study of Greek until the arrival of two Germans, Sweynheym and Pannartz, who had worked under Faust at Mainz, introduced the art of printing, while it at the same time ruined many of the copyists. A small Greek grammar compiled by Constantine Lascaris (*qv*), which appeared at Milan in 1476, was probably the first book printed in Greek.

Antiquarianism and the interest collaterally excited in the history of noble houses, especially that of the Medici, did much to attract the sympathy of their representatives to the study of the humanists, but in the earlier years of the sixteenth century a great reaction set in in Italy, and the interest of the progressive movement, as identified with Greek, next centers in Germany. At the time of Reuchlin's death (1522) Greek was taught in nearly all the German universities. But that eminent scholar had already been denounced by the seniors of the University of Basel for his temerity in there venturing to introduce the study of Aristotle in the original text, and in 1523 we find Budæus (*qv*) writing a Greek letter to Rabelais (who was, like himself, a member of the Franciscan order) to express his sympathy with his friend under the annoyance to which the latter had been subjected, in being debarred "by the Heads of your Brotherhood from the reading of Greek treatises." "We are aware," he goes on to say, "that those Greek-detesting theologians have been most zealous to abolish the Greek language, looking upon it as the test of their own ignorance, and it is on this account that we see the most worthless of them in their sermons in the churches, railing at it, and by every means bringing it into suspicion with the people, as a most execrable study and pernicious to true theology." (Smith, W. F., Vol. II, p. 489.) Erasmus (*qv*) in like manner

found himself confronted by the charge of favoring rebellion against the authority of St. Augustine. His knowledge of Greek had been acquired in Paris after his renunciation of the monastic life, it had been improved during his residence at Cambridge (1510-1514), and it was there that he made a translation of the first book of the grammar by Theodore Gaza (*qv*), which he printed at Louvain in 1516. In the same year he published at Basel the first printed text of the Greek New Testament, along with a Latin version by himself, instead of the Vulgate. His position, however, to the end of his career was that of an eclectic, for while denouncing Lutheranism as mimical to sound learning, he may be said to have educated Zwingli, whom he had taught Greek at Basel, and who, throughout his career as the head of the Reform party in Switzerland, always evinced a marked preference for the Greek patristic literature over the Latin. How well Erasmus educated himself may be seen in the critical comment which enabled him to recognize the superiority of the diction of St. Luke to that of the other Evangelists. Melancthon's (*qv*) inaugural lecture in 1518, as professor of Greek at the newly founded university at Wittenberg, marks a further advance in relation to the study of the language, by the advice which he gave that it should be pursued *pari passu* with that of Latin, by all students "who sought to grasp the substance of the involved thought rather than its shadow." In the same year he published his *Greek Grammar*. The movement at Oxford, contemporary with the visit of Erasmus (1498-1499) resulted in no traditions. Grocyn (*qv*) is said to have lectured on Greek, and he possessed a fine library of classical authors, but his lack of critical judgment is evinced in his admiration of the current Aristotle, his disparagement of Plato, and his belief in the genuineness of the *Hierarchy* of Dionysius the Areopagite. At Cambridge, on the other hand, the foundation of the Regius professorship by Henry VIII in 1540 brought the study at once into favor, and the appointment of Sir John Cheke (*qv*) to the chair still further added to its popularity. Roger Ascham (*qv*), writing only two years later, describes the principal Greek authors as being already studied with an ardor altogether surpassing what had ever been elicited by the favorite Latin classics (Mullinger, Vol. II, pp. 52-57).

Philology, as a study, was as yet unrecognized, while all speculation on the subject was vitiated by the prevalent theory with respect to Hebrew, as the original tongue from which all the others were directly, or immediately, derived. In assigning the priority to a language in a scheme of instruction, the choice was accordingly supposed to lie between Hebrew and Greek. Rabelais inclined to put the latter first, as "that without which it is a disgrace for a man to style himself scholar."

(Smith, W. F., Vol. I, p. 246), — a view which appears to have been the current one in France long after his time. Ratke, in Germany, in propounding his scheme (1612), placed Hebrew first, then the Greek Testament, and thirdly Latin. His views, however, — put forth as they were in subservience to the prejudices of Lutheranism, which regarded the Greek and the Latin classics as alike demoralizing, — gained a temporary popularity greatly in excess of their real merits, and encouraged thereby, Ratke next proposed to substitute for the laborious imitation of the classical writers, which has been the practice of the humanists, a method similar to that whereby a colloquial knowledge of German or French is gained in the present day. The consequence was that both in northern Germany and in the Low Countries the critical faculty fell into disuse, and, in the language of Mark Pattison, "the Dutch editors shunned Greek, to which they were unequal, or only attempted it to give evidence that it was a lost science" (*Isaac Casaubon*, p. 458). Comenius, notwithstanding his enlightened views with respect to practical education, inclined to a like theory with regard to Latin, and connived at a laxity in Latin prose that threatened to result in the complete disappearance of a pure and correct style (Eckstein, p. 175).

The commencement of a radical reform dates from the time of F. A. Wolf (1759–1828), who, when a student at Gottingen, devoted himself to the study of philology with a success that led to his receiving an invitation from Zedlitz at Halle, to transfer himself to that rising university, "in order," wrote the professor, "to free it from the reproach of being without a single student of the subject." Wolf's compliance resulted in a further extension of his researches to ancient history, and especially to everything that related to Greece, and the Greek language and literature, — his keen insight into the specific merits of the classic writers, both as regards style and matter, constituting an epoch in the annals of scholarship. With regard to the question of the order in which the two languages should be taken, he concluded that in all cases where the student gave evidence of an aptitude for linguistic studies, Greek should be taken before Latin, a view in which Gedike of Berlin and Herbart expressed their concurrence, urging (1801) that the Romans having been, as it were, the disciples of the Greek, it would be an inversion of the true order, alike of linguistic and of philosophic studies, to give the precedence to Latin. On the other hand, there were those who pointed out that, if Greek were taken before Latin, the requirements of the classroom would necessitate a considerable curtailment of the time allotted to the latter, and in connection with Greek, and largely under the influence of more independent research in other countries, two rival schools

began, at this time, to divide the allegiance of the learned world. On Gottfried Hermann of Leipzig (1772–1848), it devolved to retrieve the disadvantages resulting from the influence of Ratke by pointing out that the study of Greek could be profitably pursued only by the adoption of a strictly logical and rational method, while August Boeckh (1785–1867), who, after studying theology and philosophy at Halle, had been professor at Heidelberg and in Berlin, concentrated his research upon the past history of institutions, art, and archaeology. That Hermann was to some extent inspired by the example of Bentley (1662–1742) at Cambridge, is undemable, but his editions of the tragic Greek poets and of Pindar bore the impress of an originality and critical insight unprecedented in Germany, while Boeckh's *Public Economy of Athens* and *Corpus Inscriptionum Græcarum* "laid the foundation for all later research in the departments with which they were concerned" (Sandys, Vol. III, ch. 29). In the freer atmosphere of the newly founded university of Berlin, the masterly investigations of Franz Bopp (*q.v.*) created, in like manner, the study of comparative philology, and his method, as set forth in his *Comparative Grammar*, afforded new guidance in connection both with Greek and with Latin.

In the meantime the question of priority had received a practical solution in France and in England by the requirement in Paris, as at Oxford and at Cambridge, that students on entering the university should already possess a colloquial command of Latin. In these important centers, accordingly, the language itself was not taught (it being presumed that the requisite knowledge had been already obtained at the grammar school), and Éton, Winchester, Westminster, Charterhouse, St. Paul's, and Christ's Hospital vied with each other in sending up youths who already spoke correct Latin and wrote Latin verse, and were thus able forthwith to devote their time to Greek and to Hebrew.

*University Courses in Greek at Present* — It is impossible to give any statistical statement of the number of courses in Greek in the chief universities which would serve to indicate the strength of the subject in the different countries. It might be mentioned, for example, that in the German universities 142 courses were given in the summer semester of 1911, and that these were distributed among the following branches: philosophy (7), literature (66), composition (7), history (11), beginners (11), archaeology and antiquities (23); philology and epigraphy (17). But the number of students who attended the courses is not available, nor can figures indicate the quality of the work done, for the productions in any field may be more valuable when confined to a small and selected number than when largely cultivated. In France, too, there are in the sixteen faculties

of letters twenty-seven professors and two adjunct professors, assisted by twelve lecturers, but the scope of their work is as a rule not defined. Of the English universities Oxford and Cambridge are still the strongest centers for the study of the classics. Greek is studied intensively by all students who graduate in the school of *Literæ Humaniores* at Oxford and in the classical Tripos at Cambridge, and is also taken in certain groups for the pass degrees. Here, too, it is difficult to differentiate between those who give courses in Latin and those in Greek, nor would a statement of their work be significant, for much of the work is done privately with the college tutors. In the newer universities there are separate chairs for Latin and for Greek, while in some the lecturers or assistants may instruct in both subjects.

**In American Universities** -- Before the founding of the Johns Hopkins University (1876), there was nothing in the United States fully corresponding to the German philosophical faculty in the modern sense. But some advanced work was offered to graduates at Yale College from 1847, and soon after at Harvard, in classics, as in other subjects. The degree of Ph.D. for work primarily in Greek was first given at Yale, in 1863. At Johns Hopkins, Professor Gildersleeve began at once to draw able and ambitious students who previously would have gone to Germany. Gradually the strongest of the older colleges and state universities developed and strengthened their advanced courses in Greek; the University of Chicago from its first session (1892) made this one of its important departments. At present, besides the institutions already named, one might mention Columbia, Princeton, and the Universities of California and Michigan, with a few others, as furnishing good opportunities in their graduate schools for the advanced study of the Greek language and literature, as well as of Greek archaeology. At none of these is the number of students in Greek large. It should be remembered also that the American School of Classical Studies at Athens is in effect a part of the graduate school of all American universities and colleges that unite in its support, and constitutes an important part of the provision made for Greek as a university study. To that school, as to the graduate school of several of the universities, women are admitted, as well as men.

**In American Colleges** -- In America as elsewhere the line between secondary school and college, as between college (or what corresponded to it) and university, has been an unstable one. To no subject does this apply more fully than to Greek. Still it may be said that from the foundation of Harvard (1636) Greek has always been regarded as a subject to be taught in college -- required of all, in accordance with tradition, so long as any large part of the curriculum was required,

but everywhere the first of the triad, Latin, Greek, Mathematics, to be made optional. In the state universities, as these were gradually established from 1837 on, Greek was one of the subjects to be taught in the department, however named, that corresponded to the older colleges. In most of these Greek was never required; in some, as at the University of California still, it was required for the degree of A.B. only, while another degree, usually intended to be of equal value, though lacking the prestige of tradition attached to the older degree, was always provided as the crown of a parallel course for which Greek was not required. Similar parallel courses, without Greek, have in one form or another been established at all important older colleges, except where Greek has ceased to be required for the A.B. degree. But it should be remembered that in the United States no profession or public office has ever been wholly closed, even by custom, still less by law, to those who knew no Greek. The restrictions long maintained in France and Germany in this regard never had a place here. This fact is usually ignored by people who would draw parallels between America and continental Europe. Further, each college being a law unto itself, there has been endless experimenting on this, as on most, educational questions; general statements must, therefore, be very broad, and detailed statements for the entire country would require too much space. But one may say that up to about the last quarter of the last century the degree of A.B. from all but the weakest colleges generally implied more or less of Greek study in college. Since then the ratio of bachelors of arts who never studied Greek has been steadily increasing, of late rapidly. No other academic degree ever necessarily implied an acquaintance with Greek, though bachelors of divinity nearly always had studied it a little, at least in the New Testament; of course many lawyers and physicians had taken a college course, with Greek, before beginning professional study. Exact figures are not obtainable, but probably not over one tenth of American young men or young women now studying for the A.B. degree take any Greek in college, and the ratio is diminishing. Where Greek is not required for entering the department leading to the baccalaureate in arts, elementary courses in Greek, wholly optional, are regularly offered. On the other hand, the opportunities for Greek study in college, for those who wish and are prepared to take them, have been greatly increased. Early in the eighteenth century Homer and the New Testament were still the most important, in many cases the only, Greek books read. Not until the nineteenth century was the range much enlarged; American colleges then, like the corresponding institutions of Germany and Great Britain, accorded to Greek a higher esteem and a larger place than it had ever received before. At present, since colleges are

of all grades of strength, advancement, and inclination toward classical study, all grades of opportunity are offered in them, from the minimum recognized two hundred years ago, to the maximum in the ten or a dozen best. In the latter are regularly offered courses in Homer, the drama, orators, the historians, Theocritus, and Pindar. In general the college canon includes in each branch of literature portions, at least, of all the greatest books, those which have had most subsequent influence and which contain most of intrinsic literary interest. The situation in Canadian colleges is much the same, though these naturally show closer relations with English usage, and more distinctly favor, for students inclined to take Greek, earlier specialization and a wider range of reading than any in the United States, with the possible exception of Harvard.

**In Schools** — The schools of different countries have developed on such different lines that comparisons in regard to any branch of study are difficult to make and are peculiarly open to misunderstanding. And as was said above, school and the faculty of arts in the university are not always clearly distinguishable. In the following sketch of the place of Greek in the schools, only Germany, France, and England will generally be considered, as most nearly concerning America. It is impossible here even to summarize the complicated and interesting history of Greek study. For three centuries textbooks and methods of teaching, judged by present standards, were extremely defective, and results appear to have been small for the mass of the pupils. The fruitful labor of a few great scholars, the profound effect of Greek study on a few receptive and strong minds, who became, largely in consequence of their saturation with Hellenism, a powerful influence on their contemporaries and immediate successors, stand in sharp contrast with the slight tincture imparted to the majority. The intense interest in Greek during the earlier Renaissance soon declined in Italy. Political conditions never favored a high development of education there, even among the upper classes, until the establishment of the present kingdom. Ecclesiastical education, though it continued to include Greek, did not aim at the fullest mastery of the subject. It was in Protestant Germany and England that Greek literature was most highly esteemed, permeated most thoroughly the highest intellectual life, most strongly influenced the men who created the modern classics, and has held the largest place in the school training of the educated class. (See earlier section of this article.)

For *German schools* a new era began with the reorganization of the Prussian educational system after the humiliation of Prussia by Napoleon; the founding of the University of Berlin in 1810 was part of the same movement. The school which led to the university and was

intended for the early training of all members of the learned professions and all higher state officials, which was, however, open to all boys whose parents could send them, was the gymnasium. This was meant to be the stronghold and propagator of the New Humanism, the heart of which was the appreciation of Hellenism, as exemplified in all the makers of classical German literature, notably in Lessing, Goethe, and Schiller. Latin was given the largest place in the new gymnasium, but Greek stood beside Latin for the last six years of the course. And without passing through this course there was no entrance to the university, therefore none to a profession nor to high civic office. The Prussian schools, controlled by the State, were on the whole so superior that they became the general model for all other German states. Further, the privileges granted only to state schools made it impossible for good private schools for boys to grow up beside the state schools. The system as a whole amounted to a degree of propulsion toward the study of Greek such as England and America never approached, that of France was similar, but less rigid. Two large results followed. First, Greek was taught and learned with a thoroughness nowhere else equaled by so large a fraction of the youth of a country. Second, as mathematics, natural science, the native and other modern languages and literatures became more and more important for a liberal education, and yet could not be adequately recognized in schools that gave so much time to classics, the revolt against this educational monopoly was more justified and was strongest in Germany. The centralized state control made it harder than in America for public opinion to effect changes, but changes had to come. Under the present Emperor they have been coming rapidly, and are likely to go much farther, and Greek is the subject most affected by them. In two ways Greek is crowded out. First, students are now admitted to university privileges from other schools, without Greek; second, more room for modern subjects must be found in the gymnasium by restricting the time allotted to Latin and Greek. As one manifestation of the latter tendency, the plan of the so-called Frankfort system seems to promise most for the retention of Greek. By this plan Latin is not begun till the fourth year of the nine-year course, being preceded by three years of French. Greek is not begun till two years later, and is then studied intensively for four years. If this shortening of the time leads to the adoption of improved methods of teaching, along the line of the vastly improved teaching of modern languages that is now enforced in all Prussian secondary schools as in all French lycées, probably more Greek can be taught than was taught under the old plan.

In *France* the first Jesuit school was the

Collège de Clermont in Paris, later named Louis-le-Grand, now the Lycée Louis-le-Grand, founded in 1563. The schools of this order regularly gave much attention to Greek, and were the strongest educational force, alongside of the government schools, till the Jesuits were expelled from France in 1764. The statutes of the university, published in 1600 by the commission of Henry IV, show the influence of the Jesuit schools and of Sturm's system in Strasburg. While laying most emphasis on Latin, the statutes demanded considerable knowledge of Greek for admission to the upper division in philosophy. And the master's degree, including Greek, was the minimum qualification for the secondary teacher. In essence these requirements continued in force till 1793. The Revolution established the principle of universal public instruction, free in the lower stages, but the institutions intended to embody the principle attained no stability till 1808. Greek long continued to be required during four or five years in the course leading to the baccalaureate in letters, which again was prerequisite to the higher professional careers, though exemptions gradually increased. But by the regulations of 1902 a knowledge of Greek ceases to confer any formal advantage in regard to admission to any career—except, of course, that of a classical teacher. The distinguishing features of the new curriculum are these. After a preliminary course of primary study follow two successive cycles, one of four years and one of three years. In the first cycle there are two sections, one has no Greek or Latin, in the other Latin is required and Greek is optional during the two upper years. In the second cycle four groups are open, one alone includes Greek with Latin, two others include Latin with more extensive study of modern languages and of science respectively, one includes modern languages and science, without Latin. This arrangement, with accompanying privileges, goes beyond the present German system in leaving Greek to stand purely upon the popular estimate of its intrinsic worth. And unfortunately one does not gain from current reports any high opinion of the actual teaching of Greek in the French lycée. (See FRANCE, EDUCATION IN, under Secondary Education.)

In *England* the establishing of classical schools in the sixteenth and seventeenth centuries was a widespread movement, as truly popular as any such activity could be in those times. It was always recognized that many who desired higher education, and who would by it be fitted to render public service in church and state, were sons of poor parents. Hence every educational foundation provided in some form for gratuitous teaching, or partially gratuitous, of a certain number of poor boys. In all such schools Greek was a firmly established subject of study by 1660, and has continued to be so. In the latter half of the last century a

"modern side," without Greek, also became usual, and a demand for exemption from Greek for university entrance made itself felt. The newer universities do not require it, and the question is under discussion at both the older institutions. At Cambridge German or French is allowed as a substitute for Greek in the Regulations for the "Examination in Modern Languages for the Ordinary Degree," an innovation which probably foreshadows a like concession with regard to the requirements for the "Previous Examination." At Oxford, however, the proposal to make Greek non-compulsory in the cases of candidates presenting themselves for honors in mathematics and natural science was rejected in Congregation (November, 1911) by a majority of 236. As regards the preparatory schools the Report of the Curriculum Committee (1910) suggesting that Greek should not be commenced "until a boy had reached a certain standard in other subjects, such as English, Latin, and French," was laid before the Headmasters' Conference at Sherborne, but is still awaiting their formal consideration. But nowhere else is Greek more firmly entrenched in the estimation of the educated classes than in England and Scotland, thus must have for a time a conservative effect in the schools. The amount of time traditionally given to the subject, however, must certainly be diminished, and also the number of those who drop out by reason of failure to attain, before the age limit, the standard set for the successive forms. It should be added, on the other hand, that youths to whom the subject is adapted, and who take the full training of a fine English school, including verse-composition, and then honors in classics at Oxford or Cambridge, obtain a fuller mastery of the Greek language and a deeper understanding of Hellenism than is imparted by the corresponding course of any other country.

In *America*, the English colonists, following the example of the mother country, began early to found grammar schools, in which Latin should be taught, and a beginning of Greek, in the New Testament. (See GRAMMAR SCHOOLS.) Before the Revolution also the endowment of "academies" as another class of secondary schools (see ACADEMIES) had been well begun, and continued into the last century, to be succeeded by the still more popular movement for establishing free public high schools. One of the chief functions of the academy, as of the grammar school, was to fit boys for college, and hence to start boys in Latin and in the elements of Greek, the high schools were intended rather to furnish a better education for those who could not go to college. Preparation for colleges of the old type was for them always a secondary aim, and has been more and more subordinated as the other aim has broadened and turned more toward vocational training, or at least toward such teaching as would more directly facilitate bread winning. In the newer

states, of course, where the state universities have always given more attention to applied science and purely modern subjects, the high schools of each state have stood in close connection with its university, but that brings them no nearer to Greek. The great increase in the number of pupils whose home speech is not English has been a large factor in this development of the high schools. Accordingly, while many of the earlier high schools included Greek in the curriculum, few, except large high schools, now do so, and many of the largest, as in New York and Chicago, do not. In many states, as Iowa and Minnesota, no high schools teach any Greek. The surviving grammar schools and larger academies generally teach it to those who desire it. Meantime, with the increase in wealth and advance in ideals of education, the demand has latterly been growing for proprietary and endowed schools of the highest class. (See PRIVATE SCHOOLS.) This has filled to overflowing the existing schools of this sort, and has brought into existence many new ones. These are largely, if not primarily, preparatory for college and technical schools, and hence include Greek for those who wish it. They may prove to be one of the strongholds of Greek instruction, since they are in a better position for adopting improved methods of teaching than are the teachers in public schools, and their advice carries more weight with parents and pupils. Finally, it should be mentioned that the Roman Catholic Church maintains not a few colleges and schools, including some for girls, in which Greek is taught. Also, some groups of immigrants from Germany have been active in providing classical teaching for their sons. Notably the Lutherans have a series of flourishing schools more closely modeled on the German gymnasium than any others in America.

Amid the conflicting currents of life in America it is difficult to sum up the present situation with reference to Greek study, and impossible to foretell the future. The materialistic trend of the whole modern world toward money-getting is hostile to studies that seem to have no direct bearing on that. On the other hand, the deep idealistic strain and the passion for the best that are so characteristic of the race that in America is slowly forming out of many heterogeneous elements, offer ground for hope. Whatever the teachers of Greek can lead their pupils to feel, in adult life, has been good in their own mental experience, will be kept and made available for their children.

T D G

**GREEK, TEACHING OF** — It is well to begin with a clear idea of the end in view in learning Greek, as the first regulator of method in teaching it. Complete agreement as to that end there has probably never been, and in four centuries views have undergone many changes. The carefully limited statement of the Prussian *Lehrplan* of 1901 is. "An ac-

quaintance, based on adequate knowledge of the language, with a certain number of literary works of special importance for content and form, and by this means an introduction to the thought and civilization of ancient Greece." Here is not a word that suggests any other purpose in studying Greek than in studying Chinese; the official directions to teachers hardly touch upon what is really the heart of the teacher's task, they tacitly assume, in the traditional way, that learning a foreign language is a radically different process if the language is ancient. Current formulas in England and America, however various in form, fall into two classes, according as they put in the foreground the content of the study or the effect on the student. But these two conceptions, instead of being opposed to each other, are simply two aspects of one mental activity; they may be reconciled in a single statement, comprehensive and brief. The starting point for this is a great historical fact, which may be put in the words of one of the best-known scientists of England and America, Sir William Osler: "The tap-root of modern science sinks deep in Greek soil, the astounding fertility of which is one of the outstanding facts of history."

Though not always recognized, the controlling principles of our art, literature, and philosophy, as well as those of science, are Hellenic" (*American Magazine*, December, 1910, p. 247). Corresponding to this undisputed fact of history, and somehow closely related to it, though we cannot here discuss the relation, is the following psychological fact, verified in centuries of experience. For minds not unadapted to it, the process of acquiring, under good instruction, a first-hand acquaintance with the Hellenic mind, as embodied in the existing works of ancient Greeks, is peculiarly formative, enlarging, disciplinary. No educational instrument yet known can fully take the place of this, as none can take the place of mathematics. This brings us to the simple and comprehensive formula. The prime object of Greek study is to gain a first-hand acquaintance with Hellenism, as a great force in civilization, the first aim in teaching Greek is to lead pupils to a personal acquaintance with that force. The disciplinary effect, the formal training, and all desirable ends, are included in that central aim, as auxiliary or incidental to it. That Hellenic force has been profound, lasting, pervasive. Along one line it even reached the extreme Orient, long before the Renaissance in Europe. It has recently been demonstrated that through Alexander's conquests, carrying Greek art to northern India, where Buddhism arose and matured, even China and Japan received from Hellas a potent influence on their sculpture and painting. And now this influence, carried eastward to the edge of Asia, has there met the broader stream that flowed westward through Europe to America and across the Pacific. Such far-

reaching facts in the development of mankind must continue to urge all who would understand the intellectual world of to-day and the movements of history to know Hellas for themselves. And really to know Hellas is to take into one's self directly something of that original force, still unexhausted, still fertilizing the individual mind that is brought into real contact with the art, literature, and thought of ancient Greece. Such are the facts and experiences that must draw many of the stronger and more aspiring minds to this study.

When we would approach the Hellenic spirit most directly, it is embodied, first, in countless examples of Greek art still existing, more or less injured, in European and Asiatic Hellas, and in the museums of Europe and America, and secondly, in a copious literature. Where the former are accessible, as in our larger cities, no opportunity to become acquainted with them should be neglected. But for general educational purposes literature has this advantage over all other arts, that its originals can by printing be reproduced perfectly, cheaply, and in any number of examples. If we will, we can know these books nearly as well as any Greek could. Only we must first learn the language, for translations are but poor copies. In school and college the Greek language is to be taught and studied primarily as offering the only direct access to the great books. For while Euclid and perhaps a few other authors can be adequately read in translation, neither Homer and the dramatists nor Thucydides and the orators nor Plato and Aristotle can be so read. For these the content is inseparable from the original form. And unfortunately Greek is a difficult language. Its difficulties may be considered in four groups, which present themselves to students in the following order. First, an alphabet differing in part from our own. This is the least difficulty, but is serious during the first weeks. Second, a large vocabulary, far less represented in everyday English than is the Latin or French. Third, a rich inflectional system, especially for the verb. Fourth, a wide divergence from English in syntactical idiom, a divergence due chiefly to the third group of differences, the copious inflections. It is really the verb that is at the bottom of all serious troubles after the alphabet is learned, and too often the verb is neglected, with disastrous results. Taken altogether, it is not too much to say that as large a bulk of grammatical acquisition is required to prepare for the best colleges in Xenophon and Homer as that required for preparation in Latin and in elementary French and German combined. Nothing is gained by blinking these difficulties. It is better to face them, and attack them in order.

The first step in learning the alphabet is to copy out both capitals and small letters, the teacher indicating the best way of writing each where a question can arise. Some would fol-

low the cursive manuscript forms now used in Greece. This has advantages, but unless one lives in a Greek-speaking community, keeping nearer to the usual printed forms leads more directly to the main goal. Next the names of the letters should be copied out, in Greek characters, the pupil pronouncing each one aloud repeatedly. The written accents are so troublesome that one is inclined to relax the requirement of strict accuracy at first, hoping to take them up more carefully later. That is a mistake, to correct a habit of inaccuracy once acquired takes more time and effort than does accuracy from the beginning. The fundamental rules are few, and the whole subject less difficult than English accent is for foreigners. And careful pronunciation should accompany every step. This raises the question, what pronunciation? As with writing, unless one lives in a Greek community, it leads most directly to our main goal, acquaintance with the *ancient* literature, to adopt the compromise in pronunciation which is recommended in recent grammars and by the Classical Association of England and Wales. The principle of this compromise is simple: to pronounce as the Athenians did about 400 B.C., as nearly as is practicable for our classes. The latter consideration leads us to adopt substantially the modern Athenian sounds for  $\epsilon$ ,  $\alpha$ ,  $\phi$ ,  $\theta$ ,  $\chi$ , and to give  $\omega$  a closer sound than the ancient, like that of German  $\bar{o}$ , the ancient sounds in these cases would, for our classes, be so difficult as to demand for mastering them a disproportionate amount of time. For the same reason it is not thought worth while to attempt the ancient pitch accents, we pronounce them all, in the present Greek fashion, as we do the English stress accent. Long and short vowels, however, it saves time in the end to discriminate carefully, "hidden quantities" are few in Greek. To Plato no doubt our best reading would have sounded very barbarous, perhaps unintelligible. But so would our reading of Shakespeare's lines have sounded to Shakespeare; that does not make them less living to us. Some would see in this example an argument for the modern Greek pronunciation for ancient Greek. That, however, is to overlook the decisive differences in the two cases. The change in English since 1600 has not gone so deep that our pronunciation destroys all Shakespeare's rhythm, confounds the commonest words, and turns a phonetic spelling into an irrational chaos. The modern Greek pronunciation does all that for Sophocles. Considering the centuries that have elapsed, the Greek language has been conservative; some of the present characteristics began to appear before 300 B.C.; the popular speech of Greece is euphonious and expressive and has an interesting literature. But the wealth of the old literature was a constant force toward the retention of old spelling, while pronunciation inevitably changed. When, therefore, the

modern sounds of the letters are applied to the poetry of twenty-three centuries or more ago, rhythm disappears, spelling becomes chaotic, and the language far harder to acquire. For an approximate illustration in English we should take, not Shakespeare, but Chaucer. To read his lines as verse we must return as well as we can to his pronunciation; in good teaching of Chaucer that is now done.

But precision in pronunciation on the system adopted is essential. This is one item in the application of the general principle that Greek, like any foreign language, should be taught as a living speech. As for "dead languages," of course Elizabethan English is really as dead as the language of Xenophon, the latter can be made to live for us in the same way as the former, and not otherwise. That is, ear, hand, and tongue must from the first be as accustomed to Greek words as the eye, precisely as in the best teaching of modern languages. The advance of recent years in teaching these, especially in France, Germany, and England, is even more needed, and is just as possible, in teaching Greek. "Read, write, speak" was the rule of the Jesuit schools three centuries ago; the notion that Greek and Latin are to be learned merely by reading, without accompanying oral use, belongs to the nineteenth century, and is a fundamental error. How much use can be made of conversation will depend on the knowledge and skill of the teacher; more use can be made than seems possible to one who has not persistently tried for it. But the principle is not bound up in any "method", what it requires is that by every available means the ear be trained to understand Greek words when spoken, and that the student be accustomed to reproduce Greek accurately, both orally and in writing. The better the teacher's own command of the language, the more he can vary these means, and the better results he will obtain. Also the more Greek can be used for saying what must be said in the classroom, the more rapid the progress. But any teacher can insist on good reading aloud, writing from dictation, translation from another's reading, and on reciting and writing from memory both paradigms and connected passages. By such exercises, too, one gains the power to go farther in that direction. There seems to be a physiological reason for the plain fact of experience, that a foreign tongue ceases to be alien and becomes a natural and living mode of expressing thought, only when, like the mother tongue, it is firmly held by all four kinds of language memory, those of the ear, hand, and voice, as well as that of the eye. To exercise all alike from the beginning makes the learner's progress more rapid, because at each step more secure.

For mastering regular Attic inflections, and of course for obtaining any considerable vocabulary, or a fair knowledge of ordinary syntax, two things are indispensable. These are a large

amount of reading in easy Attic prose, and along with this, not after it as a special exercise, much reproductive use of the language. To both too little attention is given in American schools. Those who condemn Greek composition from the notion that this is taught as an end in itself, are attacking a man of straw; nowhere has it ever been so taught. But for learning to read any language accurately no other means can take the place of writing. And if to prepare pupils rightly for the examination in elementary French or German some two hundred pages of reading are requisite, how much Attic Greek must be read to obtain equal proficiency in the far more difficult language? Can one hundred and fifty pages of Xenophon suffice? Probably five hundred would be nearer the mark. The disproportion and the error of method in the usual practice are plain. Rereading and learning by heart, good as they are, do not meet the need. Too much rereading dulls the interest, and that is a capital mistake. What an eager young mind craves is variety, new combinations; the repetition that comes with these is more effective than twice that repetition through reviewing. For the vast apparatus of Attic conjugations, for the two or three thousand fundamental words, and for the common syntax, no single one hundred and fifty pages can offer enough combinations. Still more is this true of what we group together as idioms, the un-English ways of saying things, ways that grow naturally from the wealth of inflections, but are impossible in a language so little inflected as English. Just because they are unnatural to us, but are the warp and woof of Greek expression, the pupil must become familiar with a mass of them by meeting them in scores of variations; to repeat a few of the combinations a score of times is not enough. How to meet this difficulty is a serious problem, which we have scarcely faced, much less solved. The solution is to be sought in two places. First, a large amount of simple Attic prose, as varied as possible, should be read before the *Anabasis*. Disconnected sentences will not serve, for several reasons, first, because they are intolerably dull. And nothing read before the *Anabasis* should destroy the freshness of that interesting story by anticipating its distinctive vocabulary or its narrative, detached sentences that spoil both by anticipation are a pedagogical sin. In part the place must be filled by modern compositions. *A Greek Boy at Home*, by Dr W. H. D. Rouse (London, 1909), whose experimental work in the Perse School at Cambridge (England) has for a decade been doing much for classical teaching, can be commended from personal experience as interesting and practical, and it can be taken up in the first week. It has the merit, too, of introducing early the commonest particles and idioms of sentence connection, which play so much larger a part than in Latin or any modern language. Later some parts of

Lucian can be used; when the need is more widely realized, a wider choice of suitable texts will soon be provided in convenient editions. Secondly, we must not be afraid to postpone a little the reading of Homer, that the immortal epics may be the better enjoyed. Colleges that have classes for beginners in Greek are as directly concerned as the schools in attacking such questions as these, though it should not be forgotten that details of the solution may be much affected by the age of the class and by their previous studies. We must here confine ourselves to general principles, observing that youths of fourteen or fifteen can learn paradigms, and perhaps can learn passages by heart, more easily than those of eighteen or older, while the arguments of the orators and the thoughts of Plato's *Apology*, *Euthyphro*, or *Crito* are harder for young people to comprehend.

Three topics, under the general subject of method, still demand a few words. First, six hours a week in the class are far more than twice as effective as three hours, less than five hours a week means a sad loss of efficiency in the first year of any foreign language. The secret of the rapid strides which children make in learning German when living in Germany is not in the increased number of hours given to study, but in the increase in the number of hours of exposure to German, with the constant gentle urging, which daily life brings upon them, to listen and talk as well as write and read. The classroom is a poor substitute for all that, but is the best we have, we should make as much of it as we can. Secondly, in the writer's experience, Greek syntax makes little trouble for pupils who have really learned the inflections. It is hazy notions about these that make syntax and syntactical idioms appear hard. The thing to emphasize constantly during the first five hundred pages of reading in Attic prose is the inflections, particularly of verbs, without a firm grip on these a student can have no real knowledge of Greek, but only invertebrate and feeble notions, which were better replaced by a real knowledge of French. And a teacher must not expect this mass of forms to be fully digested until several hundred pages have been read, with much reading aloud and writing and much reviewing of set paradigms. Thirdly, what is commonly known as "sight reading," if treated as a separate exercise and as somehow distinct from right reading, is a snare and a delusion. Reading is merely taking the writer's meaning from his words, written or printed. Reading Greek or French is not different in that respect from reading English. The pages a pupil is set to read should be properly graded to his previous attainment. That being assumed, every sentence should be first read as well as possible at sight. That is, the pupil should be trained always to take the sentence as it comes, gathering the meaning as he proceeds, from all the indications before him. Precisely as, in learn-

ing the mother tongue, children enlarge their knowledge mostly by inferring from the context and the situation, so a great deal that is new can be inferred on every page. For some months all this new reading should be done in class, the teacher giving the meaning of new words when this cannot be inferred, but guiding the class to make all needed inferences that can be made on the basis of what they already know. This practice both increases speed and habituates to the right method, while it still leaves plenty for the pupil to do in revising the same passage for the next session. But any kind of reading which cultivates a habit of stopping short of a close approximation to the writer's exact meaning is vicious. The purpose of those who first gave vogue to "sight reading" was to increase the pitifully small amount of reading then usually done, the purpose at least was good.

The above outline deals only with the teaching of the language in the early stages. For a few suggestions on the teaching of Xenophon and Homer, see under those headings. This is not the place for the discussion of method in the more advanced work of the college, after a fair reading command of the language is acquired.

**GREEN, THOMAS HILL** (1836-1882) — English philosopher, was born Apr. 7, 1836, at Birkin in the West Riding of Yorkshire, the son of Valentine Green, the rector of the parish. After his schooldays at Rugby (1850-1855), he went up to Oxford, where he spent the rest of his life as a student, fellow, tutor, and professor of Balliol College, gaining first-class honors in the school of *literæ humaniores*, and winning the chancellor's prize for an essay on works of fiction. Until his election to the Whyte professorship of moral philosophy in 1878, which he held to the day of his death, Mar. 26, 1882, he served his college as lecturer and tutor in various historical and philosophical subjects. After the election of Benjamin Jowett (*qv*) as master of the college in 1870, the subordinate management of the same devolved almost entirely upon him. As an assistant commissioner of a royal commission appointed in 1864 to inquire into the education of the middle classes, Green inspected endowed, proprietary, and private schools for boys and girls, and the views expressed in his report were largely those adopted by the commissioners. Throughout his life he showed a strong interest in the reform of middle and higher education, setting forth his ideas in the report already mentioned (*Schools Inquiry Commission*, 1868,

Vol. VIII), in *Lecture on the Grading of Secondary Schools*, *The Elementary School System of England*, and *The Oxford High School for Boys*. He was also keenly interested in all practical, political and social reforms, and showed a warm sympathy for the humbler classes. His chief works are his *Introductions* to Hume's *Treatise on Human Nature* (first published 1874 in Hume's *Works*, edited by Green and Grose), *Prolegomena to Ethics*, published after his death by A. C. Bradley (1883), and *Principles of Political Obligation*, all of which, except the *Prolegomena*, are to be found in Nettleship's edition of his works, three volumes, 1885. Green's philosophical standpoint is that of objective idealism, which he developed under the influence of the German school, becoming the leader of a strong reaction against the traditional English empiricism (*qv*) as represented by Hume, Mill, and Spencer. His theory of ethics is based on a spiritualistic metaphysics: morality, like knowledge, can be explained only on the assumption that an eternal mind reproduces itself in human personality. Against utilitarianism Green teaches a doctrine of self-realization, in which, however, the social side of man's nature is emphasized: man cannot think of himself as satisfied in any other than a social life in which the exercise of self-denying will is exhibited, and in which all men shall participate. **GREENLAND, EDUCATION IN** — Greenland is a colony of Denmark, only the western coast up to 73° 30' N. and the tract around 66° N. on the eastern coast are colonized. It was first settled and named by Eric the Red (985 A. D.), who thought that an attractive name would draw colonists. His farm Brat-

tahld at Enesford (Tunugdharfik), ruins of which may still be seen, soon became the center of a settlement on the southern part of the western coast. Later on another settlement was founded farther north on the same side of the country. During the reign of King Olaf Tryggvason, Christianity was introduced, and the churches of Greenland were, with the other Scandinavian churches, joined to the diocese of Bremen. In 1124 Greenland received its own bishop at Gardar (Igahko). The government was similar to that of Iceland, an aristocratic republic, but in 1261 the Greenlanders voluntarily became subjects to the king of Norway. During its most prosperous epoch it is estimated to have had about 300 farms, 190 of which, with twelve churches and two monasteries, were located in the southern settlement. After the ravages of the Black Death in Norway (1349-1350) the Colony was neglected, and after various misfortunes the country became lost to the world and remained a blank for c 200 years until the period of explorations under Davis, Hudson, and Baffin. But communication with Greenland was extremely meager until the Norwegian missionary Hans Poulsen Egede, the Apostle of Greenland, established the settlement Godthaab on the west coast in 1721, he sought in vain for descendants of the Norsemen and began to introduce Christianity among the Eskimos. Moravian missionaries began their activity in 1733 and continued till 1900. The population of Greenland in 1908 numbered about 13,300, including 300 Europeans, almost exclusively Danes, in the Danish colonies on the western coast the natives have a strong admixture of European blood. The state of the church and public instruction is established by law of April 1, 1905, it comes directly under the Minister of Public Instruction in Copenhagen. The bishop of Sjælland is also the bishop of Greenland, which forms a separate ecclesiastical district. In 1909 there were fifteen ministers in Greenland (in 1890 only three). For the education of ministers there is a Greenland seminary in Copenhagen, where all Danish theological students who desire to become ministers in Greenland must pass an examination. The native ministers are educated first at a seminary in Godthaab and continue at the Copenhagen seminary. The school-teachers are in part educated at Godthaab, in part at special schools conducted by the higher clergy. The common branches taught in the elementary schools are religion, reading and writing of the Eskimo language, arithmetic, elementary history, and geography. All instruction in the seminaries and in the primary schools is gratis. Christianity is professed by all the population in southwest Greenland, an Eskimo who cannot read or write is rarely met with; the Eskimos have a printing office, and a newspaper in their own tongue.

**GREENSBORO FEMALE COLLEGE, GREENSBORO, N C**

An institution for the education of women chartered in 1838 under the control of the Methodist Episcopal Church, South. Collegiate, business, music, art, and expression departments are maintained. Fourteen units are required for admission to the college courses which lead to the degree of A B. There is a faculty of eighteen members.

**GREENVILLE COLLEGE, GREENVILLE, ILL**

— A coeducational institution established in 1855, originally for the education of women only. It has been under the auspices of the Free Methodist Church since 1892. Preparatory, collegiate, theological, education, commercial, music, art, and oratory departments are maintained. The requirements for admission are fifteen units of high school work. The degrees of A B, Ph B, and B S, are granted after the completion of the necessary courses. The faculty consists of nineteen members.

**GREENVILLE FEMALE COLLEGE, GREENVILLE, S C**

— Founded in 1854 under the auspices of the Baptist State Convention of South Carolina, maintaining kindergarten, primary, normal, academic, and collegiate departments. There are no stated entrance requirements. There is a faculty of nineteen instructors.

**GREENWOOD, ISAAC** (1702-1745) — Author of the first American textbook on arithmetic, was graduated at Harvard College in 1721, and was professor of natural philosophy in the college from 1728 to 1738. In 1729 he published his *Arithmetic, Vulgar and Decimal*. This was twelve years after the publication of the English book by Hodder in this country, and

fifty-nine years before the appearance of the popular American textbook by Pike

W S M

### GREER COLLEGE, HOOPESTON, ILL

— A coeducational institution established in 1891. Preparatory, normal, collegiate, business, music, and elocution courses are offered. There are no stated entrance requirements. The college courses which are based on about ten points of high school work lead to degrees. There is a faculty of twelve members.

### GREGORY, JOHN MILTON (1822-1898)

— State superintendent, educated at the Poughkeepsie Academy and at Union College, graduating at the latter institution in 1846. He was principal of academies in New Jersey and Michigan, state superintendent of public instruction in Michigan (1859-1864), president of Kalamazoo College, and of the University of Illinois. Author of *Seven Lauds of Teaching, Duty of Christianity to Educate*, and of articles in educational journals. He was editor of the *Michigan Journal of Education* from 1854 to 1859.

W S M

### GREGORY OF NAZIANZUS or GREGORY THE THEOLOGIAN (c. 325-390)

— Son of Gregory, Bishop of Nazianzus. His education was at first under the direction of his admirable mother, Nonna, later he attended the schools at Caesarea in Cappadocia, Caesarea in Palestine, Alexandria, and Athens. At the last school he studied for several years, devoting himself to oratory under the most eminent sophists of the time, Himerius and Proeresius. Like his friend Basil (*q v*), he planned to become a teacher, like him he followed the calling for a short time, and again like him he gave up the career of teacher for the ascetic religious life. He was a man little suited to the ecclesiastical career afterwards thrust upon him. Basil, who had become Bishop of Caesarea in Cappadocia, one of the most important sees in the Church, overpersuaded Gregory to permit him to consecrate him Bishop of Sasima in 361, a see which he soon forsook to act as coadjutor to his father. He afterwards went to Constantinople where he worked successfully in maintaining the Nicene faith against the predominant Arianism of that city. When Theodosius became coemperor of the East and came to Constantinople, Gregory was at once taken into high favor, was made Archbishop of Constantinople, and presided at some of the sessions of the Second General Council, A D 381. Party intrigue, taking advantage of technical irregularities in his appointment to Constantinople, forced him to resign. He left the city and spent his last years in Nazianzus. Gregory was equally great as a theologian and as an orator. As a theologian, his treatises determined some of the lines followed by Greek Christianity, as an orator, his compositions are among the

best of all time and have been taken as models by some of the greatest modern pulpit orators, notably Bossuet. His connection with education was not that of a leader. He took part in the preparation of poems to serve as Christian reading books when Julian forbade Christians to use the heathen classics, he assisted Basil in the preparation of his Monastic Rule, and his apology for his flight from Sasima has been of no small influence upon treatises on the duties and education of the priesthood, especially on Chrysostom's work, *On the Priesthood*, and the *Pastoral Rule* of Gregory the Great (*q v*). **GREGORY OF NYSSA (331-395?)** — The younger brother of Basil of Caesarea (*q v*) and one of the leading theologians of the Greek Church. He does not seem to have enjoyed the same advantages of a liberal education which fell to the lot of Basil, yet in intellectual ability he was superior to his brother and left an even deeper impression upon the theology of the Greek Church than did the better trained man. In his early life he was a teacher of rhetoric but made no great success of his work, probably on account of his inability to deal with the unruly youth with whom he had to come into contact. The edict of Julian in 361 forbidding Christian teachers to use classic authors in their instruction was for a short time a severe blow to all engaged in the work of education. Gregory certainly seems to have been quickly discouraged, for in the next year we find him, though he had previously married, in a monastery founded by Basil. His ordination as Bishop occurred in 372 when Basil put him into the insignificant village of Nyssa as Bishop in order to serve as a bulwark of Nicene orthodoxy in that part of the province of Caesarea. He was exiled under Valens, the Arian emperor, in 374 but was able to return to his see four years later. He was present at the council of Constantinople in 381 and again in 383 and 394. To what extent he remained at Nyssa is not clear, as bishops had a custom of absenting themselves from their sees for long periods and with little apparent justification. After 394 he disappears from history, and probably died soon after that date, though when, where,

## GREGORY OF TOURS

or how is unknown Gregory's great fame is that of a theologian He was strongly influenced in his views by Origen (*qv*), more so even than were Gregory of Nazianzus (*qv*) or Basil (*qv*) In spite of this characteristic, which as time went on came to be regarded more as a defect and mark of heterodoxy in a theologian, Gregory retained his place as one of the leading theologians of the Church on account of his masterly treatises on the Nicene definitions of the faith In the realm of pedagogy he takes a place on account of his work entitled *The Great Catechism*, which was a summary of the Christian faith intended to serve as a textbook to be used for religious instruction In many respects it recalls Origen's dogmatic treatise, *De principis*, but is much briefer and better rounded out in its form

**GREGORY OF TOURS** (538–294) — Bishop of Tours and historian of the Franks Gregory was born at Aversa in 538 and was educated by his uncle Gallus, Bishop of Clermont In 573, although but twenty-five years of age, Gregory was made Bishop of Tours, one of the most important sees of Gaul In this post he took an active part in the work of the Church, which in the troublous Merovingian times was the one institution of culture and education remaining in Gaul His chief work and that by which he is generally known is his famous *History of the Franks* Its style is marked by crudities of taste and grammar, which have been constantly pointed out as indicative of the intellectual degeneration of the times and the poor estate into which education had fallen It should be noted, however, that Gregory is quite aware of the fact that he does not observe the niceties of classical grammar, admits his rudeness of style, and in the first book of his history asks pardon for these faults It would appear, therefore, that Gregory enjoyed more educational advantages than might be concluded from a comparison of his style not merely with the classical authors but with writers later than Gregory himself, and that he used a current form of Latin which came more easily to his hand than the older Latin which had not yet become sufficiently distinct from the vernacular to be regarded as the object of special study In fact Gregory's language, though often rude and obscure, merely displays the characteristic features of the process whereby the classical Latin became the Romance and eventually the French language His work

## GREGORY THE GREAT

is, therefore, of interest not merely to the historian but also to the philologist and student of the history of education

### GREGORY THAUMATURGUS (c 217–270)

Pupil and panegyrist of Origen (*qv*) and Bishop of Neo-Cæsarea Gregory was a native of Pontus, having been born in Neo-Cæsarea His family was of high social rank and in early youth he was destined for a public career and was set to study jurisprudence with that purpose in view He started, while still young, for Berytus (*qv*) in Syria, famous for its school of Roman Law, but passing on his way through Cæsarea in Palestine, he chanced to meet Origen who at that time was teaching there He was so attracted by the great Alexandrine that he remained with him for five years, entirely abandoning his visit to Berytus In the end he became a Christian On leaving Cæsarea in 238, he delivered in the presence of Origen a panegyric on his master in which he gives an elaborate account of the methods employed by him in his teaching This panegyric is, therefore, a document of the first importance in the history of education and especially for the history of the early Christian schools, since it gives an elaborate description of methods employed and the curriculum followed by one who was eminent as an educator An English translation by S D F Salmond may be found in the translation of the works of Gregory Thaumaturgus in the *Ante-Nicene Library of the Fathers*, Vol VI, Am ed The subsequent career of Gregory was different from the plans of his parents He returned to Cæsarea to practice law, but in 240 was chosen Bishop of the small Christian community in the place He remained at the head of the Church for thirty years giving himself with most exemplary zeal to his work and winning large numbers to Christianity There is no evidence that apart from his work as a Christian pastor and bishop he ever taught or that he formulated any independent pedagogical theories He derives his title of Thaumaturgus, or Wonderworker, from the reputation which he seems to have acquired even during his lifetime as a worker of miracles, many of which verge upon the grossly fabulous.

### GREGORY THE GREAT (540–604) —

Bishop of Rome (590–604) No single figure is more prominent in the sixth and seventh century

than Gregory I, Pope and Doctor of the Church. No one has left behind him a more abiding mark upon the life of Western Europe. Under his lead the papacy became for the first time an important political power throughout the West. He organized its finances and consolidated its possessions. Through him the theology of St. Augustine (*q v*), the greatest of the Latin Fathers, became dominant in the West, but only so far as Gregory had appropriated it and in the form in which he had interpreted it. By his work the organization of the Church was rapidly advanced and the foundations were laid for still larger developments. It is, therefore, not surprising that he also profoundly affected the development of schools and influenced the intellectual life of the centuries that followed his pontificate. His education was thorough in grammar, rhetoric, and logic, or that general training which a young man received who was preparing for a public career. Later he studied law and at thirty was appointed *Prætor urbis* by the Emperor Justin II. He soon gave up his promising career, disposed of his patrimony in charity and the endowment of monasteries in Sicily and elsewhere, and became a monk. But the Church was not willing to see him buried in a monastery and he was ordained by Pope Benedict I before 578 and soon after was sent to Constantinople as *apocrisarius*, or papal legate, at the imperial court. From 585 he was at Rome, abbot of the Monastery of St. Andrew, which he had himself founded. In 590 he became Pope and for fourteen years administered the see of Rome as none before and few after him. His political responsibilities were no less than his ecclesiastical. His relations with the Lombards, his mission to England, under Augustine of Canterbury, his dealings with the Franks and the Eastern Empire are only some of the larger relations in which he stood with the world of his times.

As connected with education Gregory is in some respects the most important of the Church Fathers of the West, on account of his relation to the *schola cantorum* at Rome, his treatise on *Pastoral Rule*, and his influence upon the study of classical literature. These three points will, accordingly, be discussed in this order. (1) Gregory is the reputed founder of the *schola cantorum*, or Roman singing school, as well as reformer of ecclesiastical singing. Neither statement is strictly true. The fact appears to be that the *schola cantorum* was in reality the *Orphanotrophium* that had been in existence in Rome for two centuries. The principal authority for the connection of Gregory with the founding of the school is John the Deacon, a writer of the latter part of the ninth century, who says that Gregory "founded a school of singers, endowed it with some estates and built for it two habitations, one under the steps of the Basilica of St. Peter, the Apostle, the other under the houses of the Lateran Palace," and

that Gregory gave instruction in the school so founded. Indeed, the chair in which he sat while teaching, and his whip used to maintain discipline, together with the *antiphonarium* from which he taught were preserved in the ninth century. What he did, amounted no doubt, to the refounding of the school by the increase of its endowments and the impetus he gave to the study of singing as well as of other branches in the school. The reason for this increased attention to the training of the young for singers was due to the reform which Gregory carried through in the matter of singing in the divine service, by which singers were specially trained in the school for the service of the altar. Following the example of Rome, singing schools were established in many places as part of the reform in the services of the Church inaugurated by Gregory. They were, however, more than institutes of vocal culture and in them were imparted the rudiments of Latin and reading, necessary for the intelligent performance of the duties of singers. In this way, in cathedrals at least, such schools arose everywhere and were especially ordered by the council of Aix-la-Chapelle 802. (Cf. Hefele, *Concilien Geschichte*, see 409.) These schools are to be distinguished from the schools for the clergy in which higher branches were taught. (See CATHEDRAL SCHOOLS.) As to Gregory's connection with the so-called Gregorian music there is little authentic information. The first mention of a *Cantus Sancti Gregorii* is by Leo IV (847-855). It is probable that the style of music, which was developed at Rome long after Gregory the Great's day, was known as the Gregorian style of music after the great patron of the school, in the same way that the style of music cultivated in the singing school of Milan was known as Ambrosian from St. Ambrose the great bishop of Milan. In later times the interest which Charlemagne took in music made the style of the Roman school everywhere common and the whole system was generally known as Gregorian.

(2) The *Book of Pastoral Rule* may be regarded as Gregory's principal contribution to the theory of education. It is in purpose and form a study of the duties of the bishop as pastor of his flock. When it is recalled to what an extent the moral instruction and training of the times lay in the hands of the clergy and especially the bishops, the significance of a book on such a subject, written by one especially competent for the task, becomes apparent. The treatise is especially concerned with the method of meeting various moral problems that might arise. Its worth was recognized immediately and it at once became very popular. A translation of it was made into Greek by Anastasius, patriarch of Antioch, at the command of the Emperor Maurice. King Alfred (*q v*) translated it into Anglo-Saxon. By Frankish councils under Charlemagne and Louis the Pious, bishops were required to study it with

special care. In the ninth century it even became the custom to give it to bishops at the time of their consecration as a part of the ceremony. In this way it became of universal importance as determining the spirit in which moral training should be undertaken.

(3) Gregory's influence upon the study of classical literature was not helpful and he did much to create the monastic sentiment that the study of heathen writers was incompatible with Christian living. It should be said that while Gregory was well educated technically, he nowhere shows that he had any appreciation for literary beauty, such as Jerome had, and that he had not the slightest conception of literature as an art form. He knew no Greek, for though he had lived for several years at Constantinople, he saw no need of studying it. In his practical spirit there was no place for love of literary excellence. The demands of the times were so urgent, the problems before the Church so tremendous, and the Church so unsupported in withstanding the collapse of all social and moral institutions that for a Christian and especially for a leader in the Church to spend any time on the study of literature as such seemed fiddling while Rome was burning. From this point of view is to be judged the letter of sharp rebuke he wrote to Desiderius, Bishop of Vienne, an enthusiastic student of the classics and a successful teacher of rhetoric and literature. (The letter will be found in the *Epistles of Gregory*, Lib. XI, ep. 54.) It is quite possible that the rebuke was merited, a bishop had something else to do in that period than teach literature, valuable as that teaching might be. But Gregory repeats the old saying that the praises of Jove should not be in the same mouth which praises Christ. For this Gregory merely repeated what had been said before by others. (See CHRISTIAN EDUCATION IN THE EARLY CHURCH.) In his own practice, Gregory did not hesitate to write carelessly and even boasted of his contempt for rules in his dedicatory epistle (*ad Leandrum*) prefixed to his *Moralia* on the book of Job. This contempt for the simple rules of correct style and the condemnation of heathen literature as unworthy of a Christian are undoubtedly to be interpreted from the situation in which Gregory was placed, an exaggerated asceticism and a false conception of the nature of the biblical narrative. But however they are to be understood, their effect was mischievous and lasting. They gave rise to even stronger condemnation by monastic writers who attributed their exaggerations to Gregory and sheltered themselves under his example. (Cf. Gieseler, *Ecclesiastical History*, Am. ed., Vol. I, p. 490.) But it should not be concluded that because Gregory did so condemn literature and literary style that all monks had the same low opinion of literature or the same contempt for grammar. Their condemnation even was in many cases a rhetorical flourish

of ascetic writing, but such cannot excuse Gregory, who was a most downright and straightforward writer.

**GRIEFSWALD, THE ROYAL PRUSSIAN UNIVERSITY OF** — The oldest Prussian university, having been established in 1456. It is situated in the province of Pomerania and owes its origin primarily to the Burgomaster, Heinrich Rubenow, an impetus to its establishment having been given by the fact that the University of Rostock (founded 1419) was transferred temporarily to Greifswald (1436-1443). In the earliest days of the institution, the chief emphasis was placed upon the faculty of law, not more than a single chair in medicine being provided for an entire century. After a period of decline it was reestablished on a Protestant basis by Duke Philip I of Pomerania in 1539, and provision was made by him for a stated income. Again during the Thirty Years' War the institution was in constant danger of extinction. In accordance with the terms of the Peace of Westphalia (1648), Greifswald passed into the hands of Sweden, but the arrangements for a satisfactory financial basis made by the last of the Pomeranian dukes were respected by the new Swedish masters. The university struggled on until, in 1809, the property owned by the university was seized by France. The property was restored in 1813, and two years later, when the university was taken over with the rest of *Neuvorpommern* by Prussia, its property and income were left intact, as a result of which policy no contributions from the Prussian States were called for until 1874. This state aid amounts at the present day to about \$160,000 annually.

The progress of the university has been slow but well maintained during the past century. Its medical faculty was especially prominent during the middle of the last century, and its theological faculty is renowned to this day. In 1834 an academy of political science and agriculture was associated with the university, but it was replaced by an agricultural middle school in 1877. A number of new buildings have been erected since the celebration of the four hundredth anniversary of the foundation of the university, including a hygienic institute, a library, and a theological *Studienhaus* (1897).

The library, the beginnings of which go back to the gift of the valuable private collection of Rubenow, contains about 200,000 volumes and 800 manuscripts. Greifswald was the second German university to institute a summer school or series of vacation courses (*Ferienkurse*) in 1893. They have proved quite popular, and annually attract a number of foreign students, special stress being laid for their benefit on courses in German language and literature.

Among well-known former teachers may be mentioned Baum, Bardeleben, and Budge in medicine, Gass, Reuter, and Cremer in theology, Balthasar, Beseler, and Windscheid in law, Ernst Moritz Arndt (*qv*) in history, Oberbeck in physics, and C. W. Ahlwardt in classical philology. During the winter semester of 1909-1910 there were 1058 students (91 women) in attendance, including 101 auditors (51 women). The matriculated students were distributed as follows: theology 118, law 205, medicine 211, and philosophy 423. R T, JR

#### GRENADA COLLEGE, GRENADA, MISS

—An institution for the education of girls, established in 1851 and now under the control of the North Mississippi Conference. Preparatory, collegiate, music, and art departments are maintained. About ten points of high school work are required for entrance to the college which gives the degrees of A.B. and B.L. on completion of the requisite courses. There is a faculty of thirteen instructors.

#### GRENOBLE, UNIVERSITY OF, FRANCE

—Founded in 1339 by a bull of Benedict XII. It was established under the influence of the University of Naples and there was no faculty of theology. The location and size of the town, however, were not favorable to the successful progress of the university and it had practically disappeared, when, in 1452, the University of Valence was established. It was revived in 1542 and theology was included. But the institution met with no greater success than at the first foundation and in 1565 it was amalgamated with the University of Valence, in spite of much protest and opposition. At the end of the eighteenth century there seemed a probability that the University would be reestablished; but the partial reorganization did not take place until the general establishment of the University of France by Napoleon. In 1805 the faculty of law was

established and with the exception of the years 1821-1824, when it was suppressed, has continued successfully till the present time. Under the July Monarchy the *École préparatoire de médecine et de pharmacie* and the faculty of letters and sciences were established. Finally, the three faculties were organized into a university by the law of July 10, 1896. Under the direction of the *Comité du patronage des étudiants étrangers de l'Université* a special course in French language and literature was established in 1898 for foreigners, and is given throughout the year. There are now three faculties, law, science, and letters, and preparatory schools of medicine and pharmacy. The university maintains a well-attended summer school, mainly in the interests of foreign students who desire to learn French. The enrollment in 1909-1910 was 1156 students.

#### GRESHAM, SIR THOMAS (?1519-1579)

—The founder of the Royal Exchange in London and of the Gresham College, London. It is not known to what school Gresham went, but his uncle, Sir John Gresham, converted the mansion house of Holt into a free grammar school in 1546, so that the family was evidently interested in education. At an early age Thomas was sent as a pensioner to Gonville and Caius College, Cambridge. About 1535, on leaving Cambridge, he went as an apprentice to his uncle Sir John, and also became a student of Gray's Inn. Sir Thomas Gresham became the most eminent and most wealthy merchant of his time, and by raising of loans made himself a man of vast political importance. Yet he never lost his interest in literary and academic matters. He first stated the famous economic law which bears his name. He erected his Bourse or Royal Exchange in 1568, and in 1574-1575 he declared his intention to found a college in London for the free instruction of all who wished to attend the lectures. The public orator of the University of Cambridge (Richard Bridgewater) reminded Gresham of a promise he had made to give £500 either to an ancient foundation or a new college at Cambridge. An attempt was made to induce Gresham to give up the idea of a London college, which could not but be competitive to the older universities. In July, 1575, however, Gresham drew up his will, and laid down his bequest for a college to be the "Epitome of a University," and this was carried out on Gresham's death in 1579. His mansion house was, on Lady Gresham's death, to be handed over to the Corporation of London and the Mercers' Company. These

bodies were to nominate seven professors, to lecture, one on every day of the week, on the seven sciences of divinity, astronomy, music, geometry, law, medicine, and rhetoric. The salaries were to be fixed at £50, the purchasing power of which may be put at ten times that amount to-day. The professors were to be unmarried men, and to have rooms allotted them in the house, and free access to the gardens belonging to it. The rebuilding of the Royal Exchange after the Great Fire of 1666, absorbed the large revenues of the Gresham estate and the property available for the college demands, till in 1768 an act of Parliament disposed of it to the government in return for £500 a year — and an obscure room over the Royal Exchange was allotted for the lectures. In 1841 a separate building was erected at the corner of Gresham and Basinghall streets in London; and lecturers are still appointed to deliver courses in music, rhetoric, and divinity. The regulations drawn up in 1597 for the professorships are remarkable. The professors were to remember that the hearers will be “merchants and other citizens”; and therefore their lectures should be adapted to that kind of audience by being eminently practical. The divinity reader had the practical aim placed before him to “endeavor to confirm the truth of doctrine now established in the Church of England, and to refute the adverse party, and with just conscience and circumspection to sift out the true state of every controversy.” Some of the foremost scholars or scientists of their day have held professorships at the college, including Isaac Barrow, Hooke, Petty, and Sir Christopher Wren, and the relations between the college and the Royal Society were intimate. The development of better facilities for higher education in London in the last century has tended to minimize the importance of Gresham College. But the trustees seem to be showing renewed activity and propose to build a new college to accommodate 500 students, remodel the curriculum, and to found scholarships.

**GRINNELL COLLEGE, GRINNELL, IA**

— Formerly called Iowa College, a coeducational, nonsectarian institution, established in 1846 by Congregational pioneers in the territory west of the Mississippi River, under the influence of the “Iowa Band,” consisting of six young men from Yale and Andover Theological Seminar. The institution was opened in 1848, and the first class was graduated in 1854. In 1859 an amalgamation was effected with Grinnell University at Grinnell. Women were admitted in 1860.

The institution maintains the usual undergraduate courses in arts and science, and in engineering. A school of music is also provided. Graduate courses lead to the degree of A.M. for one year's work in residence. The undergraduate work leads to A.B. and B.S. The group system was adopted in 1895. There are no college fraternities. Grinnell College is one of the institutions originally accepted by the Carnegie Foundation for the Advancement of Teaching (*qv*). The present corporate title was adopted in 1909. There is a faculty of fifty-seven members. The student enrollment in 1911-1912 was 655. C. G.

**GRIPPE** (French, *la grippe*, the term *influenza* is also frequently used) — A disease due, apparently, to a minute micro-organism — the *influenza bacillus* or Pfeiffer's bacillus — which invades especially the air passages. The relation of this bacillus to the disease is, however, still somewhat in doubt.

The symptoms of gripe are protean, the complications are many, and the after-effects are often serious. The disease seems to be usually spread from one person to another. Pfeiffer's statement is generally accepted: “A development of *influenza bacilli* outside the human body (in earth or in water) is not possible. The spread of *influenza* by dried or pulverized sputum can occur only in a very limited degree. Contagion is usually connected with the fresh, still moist secretion of the mucous membrane of the nose and bronchial tubes.”

It frequently happens that ordinary colds are mistaken for gripe, and many of the so-called cases of gripe are really colds, but as a cold is a germ disease, and the means of preventing both colds and the gripe are apparently much the same, careful differential diagnosis is not as necessary as hygienic protection.

The reason that colds and the gripe are so

prevalent and so serious among school children in many sections of the United States is probably the habit of sleeping in closed rooms and of keeping the schoolroom hot and dry, and the fact that when a child shows symptoms of a cold, instead of being put out of doors he is confined in the house. In many schools, under present conditions, the spread of grippe and colds is inevitable. The one important thing is to use the sovereign preventive and remedy which is always at hand, namely, fresh air. The school should be properly ventilated, and tubercular and anemic children should be taught out of doors, and in cases where children show the symptoms of a cold or grippe, or the like, it would be well to send the child home with a note to the parent from the school physician or nurse, reading somewhat as follows: "Your child ——— shows the initial symptoms of a cold or grippe, or something of this kind. If you can make it convenient to wrap him up warmly, to take care of him out of doors, and have him sleep for one or two nights out of doors or with the windows wide open, the cold air will probably 'effect a cure.' Where there are school physicians or nurses, teachers should always bring children with suspicious symptoms to their attention. Where there are no such officials, it is well to communicate with the parents."

**GRISCOM, JOHN** (1774–1852) — An American Pestalozzian, was born at Hancock Bridge, N. Y., on Sept. 27, 1774, and educated in the Friends' Schools. He taught a district school for some years, and was principal of the academy at Burlington, N. J., from 1794 to 1807. For several years he conducted a private school in New York, and later he was professor in Queen's College (now Rutgers). The years 1818 and 1819 he spent in Europe studying foreign educational institutions and problems. He became keenly impressed with the work of Pestalozzi at Yverdon, and returned to America and became a propagandist of the doctrines of the Swiss educator. Griscom was one of the leaders in both the American Lyceum Association (*qv*) and the American Association for the Advancement of Education (*qv*). He was the author of textbooks on grammar, geography, and physics, but his most important contribution to the literature of education was his *Year in Europe* (1819). This embodied the educational results of his travels and observations in the Old World. Henry Barnard said of this work: "No one volume in the first half of the nineteenth century had so wide an influence on our educa-

tional, reformatory, and preventive measures, directly and indirectly, as this." Griscom died at Burlington, N. J., on Feb. 26, 1852.

**GROCYN, WILLIAM** (1446?–1519) — The first scholar to deliver public Greek lectures at Oxford. Educated at Winchester College and New College, Oxford, he became a fellow of the latter in 1467. In 1481 he became divinity reader at Magdalen College, holding several livings at the same time. In 1488 he went to Italy, where he remained about two years studying at Florence under Politian and Chalcondyles. On his return he took up residence at Exeter College, where he delivered the Greek lectures in or soon after 1491. Grocyn belonged both at Oxford and in London to that remarkable center of English Renaissance culture which included More, Linaere, Colet, Lily, and Erasmus. Grocyn left Oxford about 1496, and held a living in London until in 1506 he was presented to the mastership of All Hallows College, Maidstone. Erasmus always referred to Grocyn in very high terms, and once as "the patron and preceptor of us all." Although he had the reputation of being a good Ciceronian stylist, no works of Grocyn's that are of any importance are extant.

**GRONINGEN, ROYAL UNIVERSITY OF, HOLLAND** — Established in 1614 by the estates of the Province of Groningen, with the faculties of theology, law, medicine, and philosophy. Groningen had been an important seat of learning in the Middle Ages through the school of the Brethren of the Common Life (*qv*) and that at the St. Martin's Church. Toward the end of the seventeenth century the enrollment of students was over 6000, the majority, of course, being Dutch. From that time, however, a decline set in, and at the beginning of the nineteenth century there were only 200 students. With the French annexation this university became an academy of the University of France (1811), only to be reorganized as a royal institution in 1815. Since 1876 the university again began to make great progress. Buildings have been provided by the town. The five faculties are theology, law, medicine, philosophy, and letters. In 1909 the enrollment was 485 students.

**GROOTE, GERARD** — See BRETHREN OF THE COMMON LIFE.

**GROSSETESTE, ROBERT** (1175–1253) —

One of the most influential scholars, divines, and statesmen of the thirteenth century. Born of humble parentage at Stradbroke in Suffolk-shire, England, he rose to a position of great influence. His early education he may have received at the school of Lincoln, but he certainly studied at Oxford and then at Paris. In 1224 he became lecturer to the Franciscans at Oxford, and throughout his life evinced great interest in the friars, with several of whom he was on terms of great intimacy. His influence on the religious revival as Bishop of Lincoln, a diocese including about one third of England, and the democratic and national movements led by his friend, Simon de Montfort, in England in the thirteenth century, can but be mentioned here. In the field of scholarship his influence was no less, and his opportunity as the first recorded Chancellor of Oxford was unlimited. He was interested in the study of Greek and Hebrew, in Christian antiquity, in physics and mathematics, in music and agriculture. He was a voluminous and versatile writer, and in theology alone he is credited with one hundred and forty-seven *dicta* on questions of doctrine and scripture, between two and three hundred sermons, and sixty longer treatises. In a truly scholarly spirit he always, where possible, went to the sources, and in science employed observation and experiment. He devoted himself to the study of Aristotle, but with an interest in the physical rather than the logical side. He wrote commentaries on the *Sophistici Elenchi*, the *Predicaments*, the *Prior Analytics* and the *Posterior Analytics*, and *Nicomachean Ethics*, the last of which he translated probably with the aid of others. Under his direction and encouragement, Nicholas of St Alban's translated several works, including the *Testaments of the Twelve Patriarchs*. On the scientific subjects he wrote *Summa super VIII Libros Physicorum*, *On the Spheres*, a *Computus* (*qv*), and a *Computus Ecclesiasticus*. But his most important work was the encyclopedic *Compendium Scientiarum*, dealing with most of the then known subjects, and concluding with a chapter on the Unity and Simplicity of Knowledge. The metrical poem on table manners, *Status Puer ad Mensam*, which has been attributed to Grosseteste, is probably of later origin. Grosseteste's influence among his contemporaries is best attested by Roger Bacon (*qv*), an otherwise keen critic, who says "The Lord Robert (Grosseteste) alone . . . excelled all men in his knowledge of the sciences." Of Grosseteste and his friend, Adam Marsh, the Franciscan, he says elsewhere: "They were perfect in divine and human wisdom."

**GROTE, GEORGE** (1794–1871) —

Historian, born at Clay Hill, Kent, England. After a short stay at Charterhouse, he entered at the age of sixteen the bank in which his father was a partner. He continued his studies, however, devoting himself mainly to classics and philosophy. At the time of the Reform Bill agitation he ranged himself with J. S. Mill (*qv*) on the side of rationalist individualism. He entered Parliament as the representative for London, and for a time achieved some success. He retired in 1841 from active political life, and in 1843 from business. Always inspired by high democratic ideals, he devoted himself to writing a *History of Greece* as the supreme example of the workings of democratic institutions. The work was planned as early as 1822, but the first two volumes did not appear until 1845, the twelfth and last in 1856. Written with a purpose, this work is marked throughout by the democratic leanings of its author, while on the social and economic side his practical experience served as an excellent basis for interpretation. In 1865 was published Grote's *Plato and the Other Companions of Socrates*. Another work, on Aristotle, was not completed when the author died. Grote took a strong interest in the movement for spreading opportunities for university education, and was President of University College, London, and Vice-Chancellor of the University of London; he also held the position of trustee of the British Museum. He died in 1871, and was buried at Westminster Abbey.

GROTE, MRS. *Personal Life of George Grote* (London, 1873)

**GROTIUS, HUGO** (1583–1645) —

Statesman, publicist, scholar, and theologian, born at Delft in 1583. He began writing Latin verse at the age of eight, entered the University of Leyden at eleven, and at fifteen began a commentary on Martianus Capella (*qv*), which had the approval of Joseph Scaliger. He took his degree in 1598, and accompanied Olden Barneveldt on an embassy to France, where he was presented by Henry IV with a gold chain. On his return to the Netherlands he began to practice as a lawyer at the Hague, and met with unbroken success. In 1609 he wrote his first work on international law, *Mari Liberum*. In the religious dispute which broke out in the Netherlands Grotius supported the Arminian views held also by Barneveldt, who was condemned to death with the approval of the Synod of Dort in 1619. Grotius was sentenced to life imprisonment, but through the aid of his wife was able to escape in 1622, and fled to Paris, where he was pensioned by Louis XIII. In 1625 he published the most

famous of treatises on international law, *De Jure Belli et Pacis*, and a theological work, *De Veritate Religionis Christianæ*. In 1634 he entered the service of Christina of Sweden as ambassador to France. In 1645 he secured his recall to Sweden and hoped to be able to retire to his native land, since the decree of perpetual banishment passed on him in 1630 seems to have been forgotten. But he was only able to reach Rostock when he died.

Grotius was one of the most remarkable men of his age, and one of the earliest advocates of international peace. He holds an eminent position in each of the four fields of statesmanship, law, theology, and scholarship. As a scholar he is known for his translations from Greek into Latin verse, for annotations to Latin texts, for an unimpeachable Latin style. His work, *Annales et Historiæ de Rebus Belgicis*, is obviously modeled on the work of Tacitus. The *De Jure Belli et Pacis* has been translated into most languages, and on certain points is still regarded as authoritative. His views on the educational equipment of a statesman are concisely stated in the *Epistola ad Benjaminum Maurerum* (1615), a letter written to Maurer, an ambassador of the King of France, who had consulted Grotius on a course of study, presumably for himself. A man in the position of his friend, says Grotius, should be versed in philosophy, both speculative and practical, always bearing in mind that the two are complementary and that both are based on logic. He should study this subject in some simple and short compilation, Aristotle is too prolix. These subjects are to be followed by physics, especially that part dealing with the nature of our soul, and metaphysics, also in some short and concise text. In practical philosophy Grotius recommends the study of ethics and politics, through Aristotle's works and a summary of the best commentaries to be supplied by a secretary. For character studies the works of Euripides, Theophrastus, Terence, Horace (*Satires*), Plutarch, and Seneca should be read, to which might be added the *De Officiis* of Cicero. In politics the statesman should be acquainted with Aristotle, Polybius, Dio, Sallust, Cicero's *Letters* with a commentary by a Roman historian. A knowledge of rhetoric would be acquired through Aristotle, and the public speeches of Demosthenes and Cicero. A study of public law would be made in the *Laws* of Plato and Cicero, Aquinas (*Summa Theologiæ*), *Pandects*, Justinian, and contemporary publicists. Only then would the reader obtain any real advantage from a study of history in which the trend of thought rather than specific details should be followed. In history, says Grotius, it is best to work out from the present to more remote and ancient periods. Any further recommendations or details Grotius leaves to a future meeting. It will be noticed that in this rapid sketch Grotius is by no means ahead of the educational

thought of his time, which sought all training for modern conditions in the works of classical authors. But coming from a man who must have known the needs of his position from his own experience, the *Letter* acquires an increased interest.

**GROUP INSTRUCTION** — The practice of separating the children of a single classroom into groups for the purposes of alternate instruction is called the "group system" of teaching. The group method is characteristic of the ungraded school of rural communities. It is much used in cities, regardless of the fact that the teacher may have only a single grade in his charge. It gives the teacher an opportunity to work with a small number of children at a time, and permits the children to have periods of study while their fellows are reciting. The grouping of children under this plan is not the same for all the subjects, thus providing for large flexibility in adjusting to particular subjects and individuals. The drawing and music might be taught to the whole grade at once, languages and history in two groups, and arithmetic in three. A given child, because of variation in his ability in different subjects, might be taught in the more able or advanced group in history, and in the least efficient group in arithmetic. H. S.

**GROVE CITY COLLEGE, GROVE CITY, PA.** — Organized in 1876 as the Pine Grove Normal Academy, and incorporated as a college in 1884, reporting to the Presbyterian College Board. Academic, collegiate, and music departments are maintained. The entrance requirements are equivalent to fourteen units of high school work. The degrees of A.B., B.S., and Ph.D. are conferred. A postgraduate department is maintained, leading up to the

## GROWTH

Ph D degree, for which only attendance at two summer schools and work *in absentia* are required. The total enrollment in 1910-1911 was 744. The instructors number twenty-three members.

**GROWTH.** — The question of physiological growth of children is of great importance in education. Up to the present studies have dealt largely with the establishment of normal age standards of growth. Much still remains to be done in correlating growth, attainments and educational progress. During life all the organs of the body undergo important structural and functional changes, and therefore present different characteristics at different ages. The physiological development of the body does not proceed at an equal rate in all individuals, who therefore do not all reach the same physiological development at the same ages, some being accelerated in their development, while others are retarded. The stage of development of the individual may be best observed in those cases in which a noticeable anatomical or physiological change accompanies the attainment of a certain physiological condition. The progress of ossification, the eruption of teeth, pubescence, the beginning of sexual maturity, the eruption of the beard, and in later life the menopause in women, the turning of the color of the hair, the appearance of wrinkles, and the diseases of old age, offer opportunities for observations. All of these show that the uniformity of physiological development is greater in young children than in older individuals. If the distribution of stages of development were a matter of chance, they would increase proportionally to the square root of the age, but the progress of their variability seems to be quite irregular and very rapid. The range of individual differences may be indicated by those ages within the limits of which one half of all the individuals observed attain a certain physiological development. Thus, in one half of all the individuals observed there occurs —

	Years	INTERVAL Years
Birth between the limits of	0.03 and 0.03	0.06
Eruption of the first incisors	0.46 and 0.74	0.28
Eruption of the first molars	1.4 and 1.8	0.4
Eruption of the inner permanent incisors of girls	5.9 and 8.1	2.2
Eruption of the bicuspids	7.1 and 10.9	3.8
Eruption of the permanent canines	10.6 and 12.0	1.4
Pubescence of boys	13.2 and 14.6	1.4
Menarche	13.6 and 16.2	2.6
Eruption of wisdom teeth	20.8 and 23.2	2.4
Menopause	41.0 and 48.0	7.0
Death due to arterial diseases	53.7 and 71.3	17.6

It appears from these data that during school age the individual differences may be measured by a probable variability of about 2.5 years. These data refer only to the develop-

## GROWTH

ment of certain organs, but they are an indication of the variability of the development of the whole body, although nervous, muscular, osseous, etc., systems may each develop somewhat independently of the other. The measurements of children of the same age represent, therefore, individuals of different physiological developments; and these differences are the greater, the older the children. From this observation, and from the fact that during school age the variability of the stage of development remains about the same throughout, the conclusion must be drawn that during this time the individual differences in measurements, structural and functional traits, must be the greater the more rapid the rate of development and growth. Almost all measurements indicate that the rate of absolute growth of the organism is greatest at the time of birth, and shows a rather rapid decrease until the ninth year in girls and the eleventh year in boys. During the period of adolescence the rate of growth increases very much, and reaches a maximum, for girls about the twelfth year, for boys about the fourteenth year. After this the rate of growth decreases rapidly, and the skeleton has attained its full length with about seventeen years in females, with twenty years in males. Growth of muscles continues several years longer, and fat is added for many years. The central nervous system also continues to grow and develop. Owing to these conditions, the variability of anatomical, physiological, and probably also mental conditions of children is greatest during the period of most rapid growth, for girls of about twelve years, for boys of about fourteen years. These characteristics of growth have been observed for stature, weight, length of trunk, length of limbs, and measurements of the head.

Nevertheless the measurements of each organ exhibit characteristic features. Thus during childhood the limbs grow more rapidly than the trunk; the total amount of the growth of the head from birth until the adult stage is relatively small, the principal part of the development being completed before birth. The following table shows the amount of growth in stature, width of face, and length of head, from the fifth year to the adult stage, in per cent of the final size —

	MALES Per cent	FEMALES Per cent
Stature	37	33
Width of face	16	15
Length of head	9	7

The annual increments for various measurements, obtained from long series and various types, show the following values (in millimeters) —

## GROWTH

## GROWTH

AGES	MALES			FEMALES		
	Stature	Length of Head	Width of Head	Stature	Length of Head	Width of Head
5-6 . .	56	1 5	1 3	57	1 1	0 9

17	1591	853	114 6	184 8	145 2	—	—

It appears from these data that the following relations prevail between the two sexes: stature, length of trunk and of leg, and weight, of girls are smaller than the corresponding measurements of boys until the period of prepubertal acceleration, which sets in earlier in girls than in boys. As soon as this period begins, about the eleventh year, the measurements of girls exceed those of boys. With the fourteenth year the period of acceleration of the growth of

girls is passed, while the corresponding period begins for the boys, who from now on exceed the measurements of girls considerably. Length and width of head of girls are always smaller than those of boys of the same ages, and the same is true of the size of the face. At the same period, when the total stature of girls exceeds that of boys, the girls show an approach of their head measurements to those of boys, without, however, reaching them. In accordance with the more rapid rate of growth of the body as compared to that of the head, the ratio between head and body shows a constant decrease during the period of growth. The ratio is less in girls than in boys until the fifteenth year, when the continued rapid growth of the boy's body begins to depress this ratio under the value attained by the girl. The ratio between the length of the trunk and stature decreases until the thirteenth year among girls, until the fifteenth year among boys. Later on it increases again. Until the thirteenth year this proportion is about the same in both sexes. After this period the trunk of the girl is relatively longer than that of the boy. The face of girls as compared to the head is larger than that of boys, while the long-continued growth of the face of boys brings about a reversal of these relations after the sixteenth year. The cephalic index (ratio of length and width of head) shows a slight decrease during the period of growth. The head of girls is a little more rounded than that of boys. The width of hips is smaller among young girls than among boys of the same age, but it is ultimately much larger than the corresponding measure of men. All transversal diameters and circumferences continue to grow slightly for a long period.

Owing to the rapid increase of the rate of growth during adolescence, and its later still more rapid decrease, the distribution of the amounts of annual growth is very asymmetrical. For instance, among boys eighteen years old, many do not grow at all, while others show the characteristic rates of growth of boys fifteen, sixteen, and seventeen years old. The asymmetry of distribution of annual growth makes also all the series of measurements of statures, weights, etc., asymmetrical. The correlations between the various measurements are greatest during periods of rapid growth, owing to the fact that retardation and acceleration affect all the parts of the body at the same time, although not all to the same extent.

Little is known about racial differences in growth. All the series that have been taken show the same essential characteristics here described, but it may be that the periodic distribution of lesser and greater energy of growth is not quite equal in different races. It would be of great importance to investigate the question of early arrest of development of some races. This phenomenon, which might perhaps be correlated with an early arrest of

mental development, has often been claimed to exist in the negro race, but no satisfactory proofs have been given. We do not know whether there is an earlier arrest of growth of the brain, earlier synostosis of sutures, and earlier arrest of post-pubertal development of the central nervous system. On the whole, all investigations that have been made tend to show that racial differences are present in young children, although not so markedly as in the adult, and that they increase in intensity in the course of growth. They become more marked in the male than in the female.

A considerable amount of information has been accumulated in regard to the influence of environment. It has been shown particularly that better economic conditions bring about a more rapid and also a greater development of the body than occurs under less favorable conditions. Among the poor the period of diminishing growth which precedes adolescence is lengthened, and the acceleration of adolescence sets in later. Thus the whole period of growth is lengthened, but the total amount of growth during this longer period is less than the amount of growth attained during the shorter period of growth of the well-to-do. Therefore we find throughout that a young child which grows slowly will continue to grow slowly until the period of adolescence sets in. Afterwards the child that has grown slowly during the early years of childhood will grow rapidly. It is not certain to what causes these phenomena must be ascribed,—whether, for instance, climatic conditions affect the period and total amount of growth. There is some evidence favoring this opinion, but no definite data are available. It is generally assumed that nutrition exerts a direct effect upon growth. This is true in so far as underfeeding diminishes growth, but it seems plausible that in the bulk of our population the better development of man in modern times is less due to better nutrition than to the fact that hygienic conditions of childhood have improved. These are expressed in a lessened infant mortality. It seems plausible that, with the diminution of the number of diseases that attack the individual, and the consequent elimination of their retarding influences, growth suffers less interruption, and that thus the final bulk of the body is increased. The differences between social classes are great. In American cities they are partly due to differences in the racial composition of the well-to-do and the poor, the latter group containing a larger proportion of immigrants, but in Europe they occur among groups of almost the same descent. The differences between these groups are partly due to a general retardation and acceleration; so that during the period of growth, the whole group of the poor are at any given time physiologically younger than the well-to-do. For this reason the differences between social groups seem to be greatest during the period of most rapid growth.

Other causes for differences of development lie in the size of family, urban and rural environment, and other causes whose mode of action is not by any means clear. According to some authors, natural selection plays an important part in these apparent changes which develop in the series of observed individuals, but weighty reasons speak against the acceptance of this theory, particularly observations on differences in type between parents who have grown up under one environment and their children who have grown up in a different environment.

Through the investigations of Porter and Crampton it has been shown that retardation of physical development is closely associated with retardation of progress in school. To the same causes which keep back the physical development of the child must be partly due its late entrance upon school life and its slow promotions. Children who are older than the average age of their grade are therefore, on the whole, physiologically retarded children, and those who are younger are, on the whole, children accelerated in physiological development. These observations make it plausible that the assumption which has been made so frequently—that a period of slow development of the body is correlated with a period of rapid development of mental faculties, and vice versa—is not correct, but rather that rapid physical and mental development go hand in hand. If during the period of rapid growth the child has to be guarded against overexertion, both mental and bodily functions are equally concerned. The close correlation between the two emphasizes the need of proper care of body and mind.

The study of growth has been applied extensively to the work of school gymnasiums, and as a result of this work numerous tables of so-called normal growth have been published. On the whole, the results of these studies have shown that temporary practice of the body may result in a temporary strong development of parts of the body, that, however, the greater part of these results is quickly lost as soon as practice is given up.

The methods of anthropometrical work have been developed in school and college gymnasiums and similar institutions, but also by students of anthropology. The instruments used are not very complicated, and are made and sold by the makers of gymnasium appliances and by large dealers in surgical instruments. On the whole, advancement of anthropometrical work has not been commensurate with the time and energy bestowed upon it, because no adequate provision has been made for its statistical discussion. A considerable number of tables of averages and of "percentile grades" have been published, in which the measurements of each individual are so placed that the per cent of individuals of the whole series are given who have lower values of the measure-

ments than the individual in question, and it is then assumed that he should be in all respects on the same percentile grade, — an assumption that is entirely inadmissible. By far the greater number of data relating to growth have been obtained by a study of a large number of children of various ages, the so-called generalizing method. Only limited series are based on repeated measurements of the same children, the so-called "individualizing method." F B

**GRUBE METHOD** — Grube (1816-1884) published his method of teaching arithmetic (*Leutfaden für das Rechnen*) in Berlin in 1842. It was a small manual, of no particular originality or merit, but on account of the translations made by Soldan (1878) and Seeley (1891) it became an object of interest a generation ago in the United States. Grube used the "concentric circle" idea of teaching number, a phase of the spiral method (*qv*), but it was not original with him, having been suggested by Krancke as early as 1819. The idea of the concentric circle arrangement is that the child should master all number relations within the circle 1-10, then those within the circle 1-100, then within the circle 1-1000. Grube also carried the use of objective work far beyond the point where it ceased to be helpful, thus weakening rather than strengthening the number concept. He also attempted to teach the four processes simultaneously, unmindful of their difference in difficulty and importance. The result was that his method was mechanical and uninteresting, serving its chief purpose in leading many American teachers to consider with greater care the early stages of arithmetical work. It illustrates the ease with which a narrow method can be created, and the danger that arises from following such a method.

D E S

**GRUNDTVIG, NIKOLAI FREDERIK SEVERIN** (1783-1872) — Danish historian,

poet, divine, and statesman, of great importance in the history of Danish education as the inspirer and founder of the People's High Schools (*Folkehøjskoler*), and thus of the revived nationalism of the country in the last century. Influenced by a visit to England in 1829-1831 and a study of the works of Fichte, Grundtvig devoted himself to uplifting the people, who were suffering under material and intellectual depression. He saw the only remedies in a revived patriotism and a living religion. In his *Brief Writings on the Historical High School* he attacks the Latin schools of his day as "schools for death," as he characterizes them, and pleads enthusiastically for people's high schools or "schools for life." Training was already provided for all kinds of professions; the new schools should train Danish citizens. Taking as the basis of these schools the *Royal Resolutions* of 1847, which he inspired, he proposed the establishment of institutions where peasants and artisans could receive an education in the mother tongue, national songs and the national history, mythology and folklore. Above all, instruction was to be oral, for the living word is of greater value than book learning, which is deadening. Intercourse between leaders of such schools and the students was to be free and democratic, for patriotic, self-respecting, loyal citizens were to be the outcome. In addition to this cultural education some insight was to be given into the constitution, economic resources, and industries of the country, with personal contacts so far as possible.

The first school opened under the influence of Grundtvig was opened in Rodding by Professor Chr. Flor in 1848, but the present system received its impetus from the school established by Kristen Kold with Grundtvig's assistance at Ryslinge in Fühnen in 1851, until at the present time they are spread over all the Scandinavian countries, and have representatives in America.

**GUADELOUPE** — See FRENCH COLONIES, EDUCATION IN

**GUAM, EDUCATION IN** — The island of Guam, situated at the southern extremity of the Ladrone Archipelago, was ceded by Spain to the United States on Dec. 10, 1898, and on account of the convenient harbor affords a desirable naval station. By direction of the

President, the naval commander at that port assumed the government of the island. According to a census taken in 1901, the population was 9676 (4566 males, 5110 females). They comprised original inhabitants, called by the Spaniards *Chamorros*, *Tagal* settlers, and mixed people of Spanish and native ancestry. Nearly all the inhabitants could speak the Spanish language, and about 35½ per cent could read and write Spanish. They lived, as a rule, in small towns, which are said to have been in very neat condition. The American commandant at once issued orders for the government of the island, confirming such Spanish laws as did not conflict with those of the United States, and shortly after the new order of things was established, three schools were opened in the capital, Agaña, for teaching English, under the superintendence of Mr H. H. Hiatt. Similar schools were soon started in other towns, especially Asan and Agat, the non-commissioned officers of marines ably seconding the efforts of the superintendent. A circulating library was also established in the capital. The first general order relating to education issued by the commandant, bearing the date Jan. 22, 1900, placed the schools under government control. Attendance was made compulsory for the ages of eight to fourteen. Sectarian instruction was prohibited, and it was required that the English language should be the medium of instruction as rapidly as the necessary teachers could be secured. The recent progress and status of the schools are shown by the following statistics from reports made to the United States Navy Department. —

STATISTICS PERTAINING TO GOVERNMENT SCHOOLS

YEAR OF REPORT	NO. OF CHILDREN OF SCHOOL AGE	ENROLLMENT			NO. OF TEACHERS	TOTAL EXPENDITURE
		BOYS	GIRLS	TOTAL		
1908	1392	896	692	1588	33	
1909	1471			1572	35 <sup>1</sup>	\$7335
1910	1730	977	813	1790	53	8142

<sup>1</sup> Native teachers only.

On the enrollment above given an average attendance has been maintained ranging from 96 per cent in 1908 to 95.6 in 1910. The number of teachers reported in 1910 includes enlisted men detailed for the schools in outlying villages, and eleven laborers from the commandant's office. During the year a building for school purposes was constructed at Agaña, at an expense to the island treasury of \$2600. This increased accommodation will enable full-day sessions to be maintained for both boys and girls. Unfortunately, on account of the anticipated decrease in the revenues of the island, it has become necessary to drop a number of

teachers for the new fiscal year. The natives seem anxious to learn, and competent teachers are especially needed to introduce manual training. A. T. S.

**GUARINO, BATTISTA** (1434-1513) — Renaissance scholar, son of Guarino Veronese (*qv*), in whose school he gained such proficiency in learning as to be appointed professor of rhetoric at Bologna at the age of twenty-one. On the death of his father he was appointed to succeed him. Battista has left a brief account in the form of a letter to a pupil of the educational ideals and system of his father. In this work *De Ordine Docendi et Studendi* (*Concerning the Order and the Method to be Observed in Teaching and in Reading the Classical Authors*, 1459), the pursuit of letters is accepted as the most worthy object of ambition, and the educated gentleman is he who is familiar with Greek and Latin literature. The first point emphasized is the choice of a teacher who must be well bred, and, of course, a scholar. Corporal punishment should not be employed, but rather emulation and rivalry, for which purpose boys should be paired off. From the beginning perfect enunciation must be insisted on. Grammar should be taught by practical examples and drill, and should include prosody and rhythm. Greek and Latin should be taught side by side. It is interesting to compare the arguments employed for the study of Greek with those now employed by the extremist for the retention of classics. While great stress is laid on rhetoric and style, Guarino does not exclude broad reading for content, especially in history and geography, but the aim of these studies, as of philosophy and ethics, is to illuminate the references which occur in the readings. As compared with the later Ciceronian movement, the statement may be noticed that "distinction of style is the fruit of a far wider field of study" than the *Letters* of Cicero. Other valuable suggestions are the keeping of commonplace books (*qv*) and of reading aloud as an aid to clear enunciation and memory. Lastly, there is the testimony that from his father's Academy "proceeded the greater number of those scholars who have carried learning not merely throughout Italy, but far beyond her borders."

**GUARINO DEI GUARINI, DA VERONA, or VERONESE** (1374-1460) — One of the early humanist scholars and teachers. He studied in turn at Padua, Venice, and Florence.

## GUATEMALA

From 1403 to 1408 he was in Constantinople as a *famulus* in the house of Chrysoloras, the famous Greek teacher, and studied mainly under the son of Chrysoloras. On his return he opened a school at Florence, where he met with success, but in 1414 he moved to Venice, where he taught Vittorino (*q v*) Greek and entered into a lifelong friendship with him. In 1418 he was called to Verona as professor of rhetoric, and in 1429 came the invitation from Niccolò d'Este of Ferrara to act as tutor to his son, Leonello. He was permitted, as Vittorino was, to take additional pupils, day students and boarders. The presence of Guarino attracted many distinguished scholars from all parts of Europe to Ferrara, so that in 1436 the municipality appointed Guarino civic professor of rhetoric, and in 1442 obtained the rights to establish a university. Guarino continued his studies until the end of his long life. He was an eager collector of manuscripts, and on his return from Constantinople he brought back some fifty Greek Mss., and later he collected or had transcribed numerous Latin Mss. Among his writings were an elementary Latin grammar (*Regulæ Guarini*), which was widely used, and many translations, including an abridgement of Chrysoloras' *Erotemata*, and parts of Lucian, Isocrates, Plutarch (fifteen of the *Lives* and *περὶ παιδων ἀγωγῆς*), and the whole of Strabo. As a schoolmaster his aim was avowedly eloquence and scholarship (*vir bonus peritus docendi*). He divided the studies into three stages: (1) elementary, including reading Italian, Latin, and grammar, (2) grammatical, including formal grammar, and reading of the classics for content and style, Greek and Latin being taught side by side, and (3) rhetorical, consisting mainly of Cicero and Quintilian for style and composition. Guarino's educational ideals are set forth in a letter to his pupil Leonello d'Este and in the *De Ordine Docendi et Studendi* by his son Battista Guarino (*q v*).

**GUATEMALA, EDUCATION IN**—The republic of Guatemala was established Mar. 21, 1847, and the present constitution was adopted in December, 1879, but it has since been repeatedly modified. Under the direction of the president, who is elected for six years, public affairs are administered by the heads of six departments, one of which is charged with public instruction. The population of the state is nearly 2,000,000, about 60 per cent being pure Indians, and the larger proportion of the remainder half castes. In the country at large, the population of pure European ancestry is very small, but in the capital, Guatemala la Nueva, they form about five sixths of the total

## GUATEMALA

(125,000, in 1906). The prevailing religion is Roman Catholic, but complete religious liberty is guaranteed.

Public elementary schools are free, and parents are obliged by law to secure the instruction of their children, but with choice between public and private agencies. Public schools are under government inspection, and are maintained partly by local funds and partly by appropriations from the general treasury. In 1909 there were 1330 elementary schools, with 51,820 pupils, an increase over the corresponding totals for 1907 of 68 schools and 7580 pupils. The 1330 schools reported in 1909 include 174 attended by both boys and girls, thirty-one night schools, and four practical schools for boys and three for girls. In the latter schools training for trades or industries is combined with ordinary subjects and with special instruction in morals and hygiene. The Minister of Public Instruction, in his latest report (1909) dwells upon the admirable results of this class of schools, which promise, he believes, rapid increase in numbers.

In addition to the elementary schools, there is a national secondary school for boys, *Instituto Nacional Central de Varones*, a corresponding school for girls with a normal department, and a national normal school for men with a secondary department, all at the capital. At Quezaltenango there is a secondary school for boys, and at Chiquimula one secondary school with a normal department for young men, and a normal school for young women. In 1909 1202 students (758 boys and 444 girls) were enrolled in these secondary and normal institutions. The number of students in the normal school and in normal departments included in the foregoing total was seventy-one. In addition to the public schools and institutes, the chief cities are well supplied with private schools.

Higher education is represented by a school of law with 49 students in 1909, and a school of medicine and pharmacy with 135 students (94 medicine, 41, pharmacy). The school of engineering was temporarily suspended pending the erection of new buildings for the military school, of which it will hereafter be a part. There are also at the capital a national school of handicraft for women, a national conservatory of music, and a school of art. The national library contains about 20,000 volumes.

The public appropriation for education in 1909 amounted to 2,526,015 pesos (\$885,146), which was a little less than 7 per cent of the total appropriation for all purposes. A. T. S.

**GUIANA, EDUCATION IN** — British Guiana, with a population of 304,000 in 1909, had 223 public schools, attended by 33,888 pupils. These schools were supported in part by local funds and in part by government grant, amounting in the year named to £25,274 (\$116,370). The wealthy residents of Georgetown, the capital, and the owners of the rich sugar estates employ private tutors for their children or send them to private schools.

Dutch Guiana has a population of about 81,000 exclusive of negroes, and in 1909 reported twenty-three public schools with 2580 pupils and thirty-seven private schools with 4993 pupils. There are also boarding schools maintained by the religious denominations, Roman Catholic, Moravian, etc. A T S

**GUILFORD COLLEGE, GUILFORD, N C.** — A coeducational institution founded in 1837 by the North Carolina Yearly Meeting of Friends as the New Garden Boarding School, and re-chartered in 1888. Preparatory and collegiate departments are maintained. The entrance requirements to the freshman class are equivalent to about twelve points of high school work. Degrees of A B and B S are conferred. The faculty consists of fourteen members.

**GUILFORD, NATHAN** (1786-1854) — Lawyer and legislator, active in the establishment of the common school system in Ohio, was graduated from Yale College in 1812. He was for a few years principal of a classical school at Worcester, Mass., and then engaged in the practice of law in Ohio. As a member of the Ohio legislature he was active in the enactment of the first general school law (1821). From 1818 to 1825 he published *Solomon Thrifty's Almanac*, the forerunner of such publications in the United States, extensively used between 1825 and 1850 for the spread of doctrines of common school education. Guilford's almanac contained the calendar, the "weather" predictions, astronomical changes, advice to farmers, and on every page something about the value of education and the need of common schools in Ohio. He was also the author of an arithmetic and a spelling book. W. S. M.

**GUIZOT, FRANÇOIS PIERRE GUILAUME** (1787-1874) — French historian, man of letters, orator, and statesman, and member of many French academies. He was minister of public instruction from 1832 to 1837, except for brief intervals in 1834 and 1836. Under his ministry the whole scheme of primary instruction was entirely reorganized, higher primary schools were established, the departmental normal schools were put upon an entirely new basis with more effective control by the central authorities; the office of primary inspector was created, and a fresh and lasting impetus was given to the cause of popular education. His circulars to prefects, rectors, inspectors, and teachers form a veritable treatise on education. These were still further reinforced through the columns of the *Manuel général de l'instruction primaire*, which he established with the view of keeping the teachers in touch with the newer educational methods. Among the better known of his historical works are: *Histoire générale de la civilisation en Europe depuis la chute de l'empire romain jusqu'à la révolution française* (1828), *Histoire générale de la civilisation en France depuis la chute de l'empire romain* (1830), *Histoire de la révolution d'Angleterre*. **GUSTATORY SENSATIONS** — Sensations derived through the organs of taste. There are four qualities of such sensations; namely, bitter, sweet, sour, and saline. To these four qualities are sometimes added two others, which are, however, of doubtful character, namely, metallic and alkaline. Different parts of the tongue have different susceptibilities to these qualities. Thus the tip of the tongue receives sweet tastes more easily than others, while the back of the tongue is more sensitive to bitter.

C. H. J.

**GUSTAVUS ADOLPHUS COLLEGE, ST PETER, MINN** — See LUTHERAN CHURCH, EDUCATIONAL SYSTEM OF, IN UNITED STATES

**GUTHRIE, THOMAS** (1803–1873) — Scotch preacher and philanthropist, born at Brechin. At the age of twelve he entered Edinburgh University, where he studied for ten years, first taking a general course, then theology and medicine. This he followed up by study at the Sorbonne in Paris, where he took up natural philosophy, chemistry, and anatomy. He was ordained in 1830, and very soon came into prominence as an influential preacher. When located in Edinburgh, he devoted himself to social work and established savings banks, Sunday schools, and education. His work in the last field gives him a place of importance in the history of British education. Guthrie disclaims the title of founder of Ragged Schools (*qv*) in Scotland, giving the credit to the Sheriff of Aberdeen, Mr. Watson. However that may be, it is certain that by his writings Guthrie did more than any other man to spread the idea of the Ragged Schools (*Pleas for Ragged Schools*, 1847–1849). His work among the poor had opened his eyes to the fact that while the provision made in poorhouses, hospitals, asylums, and free schools reached a large majority of the population of Edinburgh, nothing was done for the very lowest classes — the shiftless, drunken, immoral beings who drove their young children on the streets to beg and steal. For the adults Guthrie was not so very much concerned, except that he strongly advocated a limitation on the facilities for obtaining drink, but the young must be taken in hand, for prevention is better than cure. These children needed food and clothing first and education afterwards, hence the need of special schools, or Ragged Schools, to deal with them. These schools were to find food and shelter, to bring back the poor waifs by sound religious education, and to fit them for some vocation by industrial training. Such a system would not add to national expenditure, but would reduce the cost of maintaining police, courts, magistrates, jails, and penal settlements. The "Original Ragged Schools" were established in Edinburgh in 1847, and spread rapidly to other Scotch towns, and in his *Third Plea* (1860) Guthrie was able

to report the disappearance of juvenile beggars and a decrease in juvenile crime, and to point to respectable mothers and fathers who had been reclaimed by the Ragged Schools. No better testimony to the affection in which Guthrie was held can be pointed to than the remark made by a girl at his funeral, "He was all the father I ever knew." Guthrie edited the *Sunday Magazine* from 1854 to his death, and contributed frequently to *Good Words*.

**GUTS MUTHS, JOHANN CHRISTOPHER FRIEDRICH** (1759–1839) — Physical educator; was born at Quedlinburg and obtained his early education in that town, studied theology, mathematics, physics, history, and modern languages at the University of Halle for three years, became private tutor in the family of a physician, and in 1785 accompanied two sons of the latter to Salzmann's school at Schnepfenthal, where he remained in active service as a teacher until a short time before his death. Guts Muths took charge of the boys daily and led them in foot races, vaulting, jumping across a ditch, jumping for height, forced marches, throwing at a mark, estimating with the eye the distance from one place to another, walking on the thin edge of a plank, lifting with a staff a weight moved nearer or farther from the hands according to one's strength, skating, swimming, sliding, etc.

He kept accurate records of each boy's progress from week to week. To the most diligent and proficient boys he taught riding on horseback, and the use of firearms. He also paid much attention to matters of diet, clothing, personal cleanliness, and ventilation of sleeping and study rooms. He encouraged walking, work in the garden, and other outdoor activities. Guts Muths exerted a powerful influence on the development of physical education, by his fifty years of teaching and by his writings on the subject.

His two most important books are: *Gymnastik für die Jugend, enthaltend eine praktische Anweisung zu Leibesübungen. Ein Beytrag zur nothigsten Verbesserung der körperlichen Erziehung. Spiele zur Übung und Erholung des Körpers und Geistes, für die Jugend, ihre Erzieher und alle Freunde unschuldiger Jugendfreuden. Gesammelt und praktisch bearbeitet von Guts Muths, Erzieher zu Schnepfenthal* (1796). These two books passed through several editions, and have been translated in many languages. They were the first modern manuals on the subjects of gymnastics and play.

**GUYAU, JEAN MARIE** (1854-1888) — Poet, philosopher, and sociologist, who in a short life of thirty-three years made some valuable contributions to knowledge. When only nineteen he was crowned by the Académie des Sciences Morales et Politiques for his work, *Mémoire sur la Morale utilitaire depuis Epicure jusqu'à l'École Anglaise* (1874). Until his health broke down completely he taught philosophy in the Lycée Condorcet. In his many philosophical works he emphasized the practical and the social as the best standards of criticism. Philosophical problems should accordingly be stated in terms of society. It is from this point of view that his chief pedagogical work, *Education et Hérité* (1887) was written. "Man being made to live among men," he writes, "we cannot go too far in the process of moulding the child for social life." The title of this work is somewhat misleading, for very little attention is given to heredity beyond a brief inquiry into the instinctive equipment of the child on which the educational process may be built up. Guyau offers some sound criticism of the French system of examinations, and gives a comparative sketch of secondary education in England, France, and Germany, and also draws illustrations from American practice for the training of initiative. He accepts the definition of education as harmonious development, and discusses the place of physical, moral, civic, and intellectual education. On instruction he says "teaching must never be a matter of memory, erudition, or pure knowledge, but rather of intellectual, moral, and civic training." In the earlier part of his book he devotes some attention to suggestion as a method of training in right habits. The work on the whole is a valuable appendix to Spencer's *Education*. Guyau also wrote a series of textbooks for use in elementary schools for children from five to eleven, dealing with moral instruction. *L'Année enfantine*, *L'Année Préparatoire*; *la première Année de Lecture Courante* (*Education, Instruction, Civisme*, one volume for pupils and one for teachers). Two readers on the basis of the reading-writing method were also written by him (*Méthode Guyau*, *La Lecture facilitée par l'Écriture*). Among his philosophical works may be mentioned *La Morale anglaise contemporaine*, *L'Irreligion de l'Avenir*, *L'Art au point du Vue sociologique*. His best known poetical work is the *Vers d'un Philosophe*.

**GUYOT, ARNOLD HENRY** (1807-1884) — Geographer, born at Neufchatel, Switzerland, on Sept 28, 1807. He was educated at the College of Neufchatel and the University of Berlin. He was for ten years professor of physical geography in the college at Neufchatel, and came to America in 1848. For six years he was employed by the Massachusetts State Board of Education as lecturer on geography in the state normal schools at Westfield, Framingham, Bridgewater, and Salem. He was professor of physical geography at Princeton University from 1854 to 1884. He was greatly influenced by Karl Ritter during his studies in Germany, and he brought to America the first rudiments of geography as a science. The textbooks of Guyot were the first to present the study of geography as a science to the English-speaking world. His works include *Earth and Man* (1849), *Geographical Teaching* (1866), geography textbooks for elementary and secondary schools, and many maps and charts. W. S. M.

**GYMNASIUM** — Originally applied to the exercise ground or public training school maintained, as for example, at Athens, not only for the ephebi, but for all men of military age, this term by a process of transference came to be used in the sense now usually attached to it, i.e. an institution for higher education. (See GREEK EDUCATION, under the caption Educational Practice.) Though the gymnasium was free, the teachers and trainers in gymnastics were paid, and as the poorer citizens had to earn their own living, the Athenian gymnasium, like the modern university, came to be chiefly frequented by the well-to-do. There being plenty of leisure between the exercises, and the spectacles attractive, the gymnasia tended to become fashionable lounges, in which the leisured class spent a large portion of its time. The older men naturally became spectators and critics rather than active performers. Among them developed the walking and talking clubs, which were the origin of Greek schools. Here the Sophists met and discussed the laws

of nature and of art, and practiced intellectual as well as physical culture. In the suburban gymnasium, called the Academy (*ἀκαδημία*) after the local deity or hero Academus, the sophist Plato started his discussion forum, or courses of free lectures, which, when at his death he devised his neighboring house and garden to his pupil, Speusippos, developed into an endowed University College. Hence our modern Academies (*qv*). In another gymnasium, the Lyceum, Aristotle, one of Plato's pupils, established his lectures, open to the inner circle only in the morning, and to the public in the afternoon. Hence the French *lycée*. The term "gymnasium" itself apparently is first used as equivalent for school only in a Greek epigram of uncertain but probably late date in the literally exact phrase "the schools of the Academy" and the metaphorical phrase "in the school of Homer" (*ἐν Ὅμηρῳ γυμνασίῳ*).

In Latin the term is not used simply as equivalent to "school", but as the locally correct term in such phrases in Cicero as "all the gymnasiums and schools of the philosophers." The Romans despised gymnasia. Until the time of Nero there were none in Rome. In the Middle Ages, the gymnasium, both thing and term, was unknown, except to one or two exceptionally learned writers, such as Matthew Paris, who described the school kept by Lanfranc at Bee as a gymnasium. But with the Renaissance the passion for Greek made the name reappear. Knighton describes a Lollard conventicle as a gymnasium, *i.e.* school, of heresy. The coming of Manuel Chrysoloras (*qv*) to teach Greek at Florence in 1396 and at Pavia in 1400, and the consequent passion for the study of Greek made Greek terms fashionable. Hence already in a letter written in 1422 Guarino of Verona uses "gymnasium" as the equivalent of "school," and speaks of Cicero as flying with the highest glory through all the schools of Italy (*gymnasia Italorum*). Vittorino da Feltre (*qv*) called his school the *Gymnasium Palatinum* or Palace School. This school became the model for many, and so *Ginnasio* became the common term in Italy for a public school of the humanist type. It is possible that the prominence given in this school to physical culture, games and sports being cultivated almost as much as in our modern public schools and universities, may have partly suggested and justified the use of the term "gymnasium." From Italy the term was transported into Germany, and seems to have been first used of the great Netherlands schools, which, alike in the numbers attending, the age to which the pupils stayed, and the subjects of instruction, were almost as much universities as schools, *e.g.* the schools connected with the Brethren of the Common Life (*qv*), Emmerich, 1474, and Deventer under Hegius and Luttich or Liège in 1498. These schools became the model for the great Reformation gymnasium founded, or rather reconstituted

by John Sturm (*qv*) at Strassburg under the control of the Town Council in 1538. It was probably the fame of this school that finally stamped the term "gymnasium" on the German language as the technical term for the great high schools in which the classics formed and still form the main subjects of instruction.

In England the term "gymnasium" never became popular. It was occasionally used by way of grandiloquence, and schoolmasters were sometimes absurdly termed *gymnasiarcha*, especially in epitaphs, just as in the new cathedral schools of Henry VIII they are termed *archididascalus* and *hypodidascalus* (which one learned antiquary translated into "master of the horse"). One learned person who died master at Fotheringhay, having been second master at Eton, whence he fled from the Roman wrath of Mary, even went so far as to describe himself on his tombstone as *paidotriba*, the term applied to the gymnasium official who rubbed the youth down with oil. But as a rule the common-sense Englishman stuck to the simple and ancient "grammar school" (*qv*). A. F. L.

**GYMNASIUM** — The equipment of a modern educational institution is not complete without a gymnasium. The provision of a special place devoted to the physical education of youth is not an innovation of modern times, for gymnasia occupied a very important place in Greek education (*qv*) and it is interesting to note that the use of the term in the scholastic sense has been retained in Germany, while the French *lycée* recalls the Lyceum, the gymnasium where Socrates and Aristotle met their disciples.

"Gymnasium" as a term in modern English education dates only from the introduction of physical training under cover into English schools. Probably the earliest building used as a general gymnasium in England was the hall for physical training, furnished with giant's strides, parallel bars, leaping horses, ladder, ropes, and the like, known as Mohammed's Gymnasium, established at Brighton about 1848. To this the numerous preparatory schools which then flourished abundantly in Brighton resorted for an hour twice a week or so. In Germany in 1870 gymnasiums were recognized by law as an essential part of the equipment of public secondary schools. But in England physical culture had for more than a century at all events, and perhaps for longer, been developed by games, such as cricket, football, and hockey. In England though some of the new public schools had gymnasiums, that at Rugby College being built in 1859, and at Marlborough College made out of a covered playground in 1869, they did not reach the old schools, now become a recognized requirement of a well equipped secondary school, till the last decade of the twentieth century. Even now in the great Public Schools and the grammar

schools situate in the country or country towns, with ample playing fields, the gymnasium plays an insignificant part in school life

#### A F L

The first gymnasium connected with an educational institution in the United States was that of the Round Hill School, Northampton, Mass., built in 1825. The first college gymnasium was one fitted in a hall of one of the Harvard College buildings in March, 1826. Outdoor gymnasiums were established at Yale in 1826, and at Williams and Amherst and Brown in 1827. The wave of interest in gymnastics which was responsible for the erection of these gymnasiums had passed by 1830 and was not revived until 1860, when Harvard, Yale, and Amherst built new gymnasiums, and were followed by other colleges. Except for a temporary check during the Civil War, the building of gymnasiums has gone on steadily since 1860, and nearly all colleges and secondary schools and many elementary schools are now equipped with them. The size, equipment, and cost of gymnasiums vary over very wide limits according to the size and financial resources of the different institutions. There are several college gymnasiums that have cost more than \$200,000.

A typical gymnasium building includes one large hall with suspended running track, smaller rooms for boxing, fencing, wrestling, handball, baseball winter practice, rowing on machines, etc., offices and examination room, locker rooms, bathrooms, and swimming pool. In planning a gymnasium building, the first consideration is the dimensions necessary to accommodate the number of students in the institution when the building is erected and to provide for the probable increase in twenty or twenty-five years. The rectangular form is better than the square for the main hall. A room 40 by 60 feet is the minimum size in which satisfactory work can be done. A gymnasium of this size would be sufficient for an institution with one hundred students. The size should increase approximately 500 square feet for every 100 additional students; thus an institution with 1000 students would need a gymnasium 70 by 100 feet. The height of the ceiling should be at least 22 feet in a gymnasium 40 by 60 feet and increased approximately by one foot for every additional 500 square feet of floor area.

The bottom of the running track should be at least 10 feet from the floor and the surface of the track at least 8 feet wide and curved to facilitate turning corners. The number and size of accessory rooms for special forms of exercise would vary with the number of students to be accommodated. With a small gymnasium 40 by 60 feet, it would be enough to have a baseball cage about 20 by 70 feet, a handball court 15 by 30 feet, and a room about 20 by 30 feet for other purposes. With a gymnasium 70 by 100 feet, a cage 30 by 100 feet, four hand-

ball courts, and three or four rooms 20 by 30 feet would furnish adequate equipment. All these rooms should have a height of at least 15 feet. The locker rooms should have an area of approximately four square feet for each locker when lockers are arranged in double tiers. The best modern bathrooms in gymnasium buildings are equipped with shower baths only, each shower having a single mixing valve. The number of showers necessary for one hundred students is about eight and two more showers for each additional one hundred students. The administrative office, director's office, and examination room should be arranged en suite in the central part of the building. The latest college and school gymnasium buildings have a large hall or room, near the entrance, in which the athletic trophies, banners, and team photographs are displayed.

There is no building in the equipment of an educational institution where adequate heating and ventilation and absolute cleanliness are so important as in the gymnasium building. Scientists have demonstrated that a man exercising vigorously vitates the air about ten times as much in a given time as when sitting at a lecture or recitation. The failure to take this fact into consideration when planning gymnasium buildings is largely responsible for the bad air usually found in gymnasiums. The air should be washed, heated, humidified, and pumped into the gymnasium in sufficient quantity to supply 100 cubic feet a minute for each individual using the room. The installation and operation of heating and ventilating equipments adequate to do this work involves a very large expense, but it is unwise economy to curtail expenses in this direction. The temperature should be maintained at 62 to 64 in rooms devoted to exercise and 72 to 74 in locker rooms and bathrooms. The cleaning of the gymnasium, locker rooms, bathrooms, and other accessories is equally important. Every part of the building should be cleaned daily, the floors washed frequently and the gymnasium mats kept free from dust by the use of vacuum cleaners. With adequate ventilation and absolute cleanliness in a gymnasium building, there is no appreciable difference in the physiological effects of indoor and outdoor exercise.

**Gymnasium Equipment.** — The selection of a proper equipment for the gymnasium of a school or college should receive the most careful attention. The essential points to be considered are: First, to supply enough apparatus for the largest class to be taught; second, to have all the apparatus so constructed that it may be easily and quickly set up and removed; and third, to distribute the apparatus from the standpoint of practical class management rather than architectural expediency.

A typical equipment for a school or college gymnasium in which the largest classes have sixty students would include the following

2 vaulting bars, 2 horizontal bars, 2 parallel bars, 2 horses, 2 bucks or vaulting boxes, 2 boms, 2 horizontal ladders, 8 climbing ropes, 30 stall bars, 2 pairs jumping stands, 4 inclined boards, 2 springboards, 2 pairs flying rings, 8 traveling rings, 6 mats, 5 × 10 feet, 4 mats 3 × 8 feet, 1 pair basket ball goals, 2 basket balls, 1 indoor baseball outfit, 6 medicine balls, 10 chest weights, 2 neck machines, 2 rowing machines, 60 pairs dumb bells, 60 pairs Indian clubs, 60 wands, and a piano. The cost of such an equipment would be approximately two thousand dollars.

If the gymnasium is to be used by girls only, the horizontal bars, horses, and parallel bars may be omitted.

The three largest manufacturers of gymnasium equipment are the Narragansett Machine Co., of Providence, R I., the A G Spalding Co., of Chicopee Falls, Mass., and Fred Medart of St. Louis, Mo. G L M

**GYMNASTIC TEACHERS** — See PHYSICAL DIRECTOR

**GYMNASTICS** — The term as used by the Greeks applied to all forms of physical exercise such as calisthenics, running, jumping, wrestling, boxing, dancing, and throwing the javelin and discus. After the long period of neglect of organized physical instruction during the Middle Ages, systematic exercise in various forms found a place in the new schemes of education. The universal and ineradicable impulse of all healthy children to play, and the appreciation on the part of educators of the important function of motor training in education, are responsible for the increasingly large place accorded to physical exercise as an integral part of educational procedure since the days of Vittorino da Feltre (*qv*).

The differentiation of the forms of exercise into gymnastics, games, and athletic sports occurred at the end of the eighteenth and the beginning of the nineteenth century. It was during that period that Guts Muths, Jahn, and Spiess (*qv*) developed the German system of gymnastics. Ling (*qv*) founded in Sweden the system of gymnastics which bears his name, and athletic sports and games were taken up in the colleges and preparatory schools of Great Britain. There are two main classes of gymnastic exercises: first, calisthenics (*qv*), which includes free movements of arms, legs, trunk, etc., exercises with dumb bells, wands, bar bells, Indian clubs, rings, hoops, balls, etc., marching, and dancing. Second, apparatus gymnastics, which includes parallel bars, vaulting and horizontal bars, horse, buck, vaulting box, stall bars, jump stands, ropes, poles, ladders, and many kinds of developing appliances, such as chest weights, and other

machines built on the principle of weight and pulley or friction.

The main difference between gymnastics and athletics (*qv*) is one of aim. The aim of gymnastics is discipline or training for its effect upon the health, normal development, and general efficiency of the individual. The chief aim of athletics is pleasurable activity for the sake of recreation, in the athletic games of boys and young men we see the highest and fullest expression of the play instinct. While the characteristic aims of gymnastics and athletics are essentially different, some of the most important results of physical training are secured from both forms of activity. This is true especially of the hygienic effects of muscular activity upon the circulation, respiration, digestion, assimilation, and excretion. These effects vary over wide limits according to the kind of exercise selected.

In considering the educative value of gymnastics and athletics the most important principle is, that neither of these activities can serve as a substitute for the other. Each contributes some essential parts of a complete physical education. Gymnastic exercises are largely subjective in character, they serve particularly to stimulate normal physical development, promote good carriage and easy coordination in motion and locomotion. Every gymnastic exercise is given for a definite purpose. The object may be to secure motor coordination, hygienic benefit, or some æsthetic effect. In this respect, gymnastics differs radically from athletic exercises, for in the latter the primary object is always to produce some effect outside of the individual, as hitting a ball, throwing an object as far as possible, or reaching a goal before an opponent. The effect of such exercises upon the individual is always incidental and secondary. Another advantage of gymnastics is, that selection based on scientific principles of anatomy, physiology, and mechanics makes it possible to adapt each exercise to the particular needs of the individual, with a view to producing the effect desired. The educative, hygienic, and æsthetic effects of exercise are susceptible of definite control in gymnastics, but in athletics the effects produced on the individual are indefinite and accidental. The particular effect produced by gymnastics depends partly upon the movements selected, but mostly upon the manner of their execution. The best hygienic effects are produced by adapting the movements to the strength of the individual, bringing into play the large muscles of the trunk and thighs, and accompanying the exercise with music, which adds pleasure to the work. The educative effects are best secured by careful selection and sequence of exercises suited to the state of psycho-motor development of the individual, and by a method of teaching which demands accuracy, precision, and speed in execution. The æsthetic effects of form, carriage and grace

## GYMNASTICS FOR GIRLS

of motion and locomotion result from gymnastic dancing and other exercises of the same type. The recreative value of gymnastics depends upon the ability of the teacher to make the work interesting, and in a measure upon the attitude of the student toward the work.

In general, the relative effects secured from gymnastics and athletics are as follows —

GYMNASTICS	
PRIMARY EFFECTS	SECONDARY EFFECTS
Educative	Organic (vigor)
Hygienic	Recreative
Æsthetic	Psycho-motor
	Moral
ATHLETICS	
PRIMARY EFFECTS	SECONDARY EFFECTS
Organic (vigor)	Educative
Psycho-motor	Hygienic
Recreative	Æsthetic
Moral	

It is very evident from this table that gymnastics constitutes an essential part of a rational scheme of physical education. The results obtained from gymnastic training vary widely for the same reasons that results vary in all branches of education. Poor teaching and inadequate facilities always produce unsatisfactory results in gymnastics as in any other subject. The need for systematic psycho-motor training and vigorous muscular activity for organic development tends to increase as life becomes more complex and specialized. The growing appreciation of the physical basis of human efficiency cannot fail to bring about increased recognition for gymnastics in the school curriculum, more competent teachers, and increased material equipment. G L M

**GYMNASTICS FOR GIRLS** — In all schemes of education, the tendency has been to provide better facilities and a more extensive curriculum for boys than for girls. This has been true particularly in regard to physical training. In Germany, England, and the United States various forms of physical training were provided for boys, while this subject was entirely neglected in schools for girls. Adolf Spiess, the founder of German school gymnastics, was the first to advocate gymnastic training for girls, but the traditional idea that womanly deportment is in contradiction to exercise has hindered the development of physical training for girls. Organic vigor and psycho-motor development are as essential to girls as to boys. The results to be accom-

plished are the same, but the methods employed must vary because of physiological differences in the two sexes.

The gymnastics best suited to girls include marching, calisthenics without hand apparatus and with wooden dumb bells, wands, bar bells, Indian clubs, rings, hoops, etc., simple exercises in vaulting and climbing (omitting, in general, all exercises requiring support of the body on the arms for more than an instant), easy exercises in jumping, and dancing. Æsthetic and folk dancing constitute one of the most valuable forms of physical training for girls of all ages. By means of judicious selection and adaptation, it is possible to secure from dancing most of the essential values of exercise, such as organic vigor, psycho-motor training, and recreation. Girls need also the training that comes from participation in athletic sports and team games. The qualities of courage, self-reliance, loyalty, and capacity to cooperate with others and subordinate personal interests to the interests of the team which result from participation in team games and sports are as desirable for girls as for boys. This training is especially valuable to counteract the tendency of some girls to be sensitive, introspective, and live too much on the subjective side of life.

In general, girls under twelve or thirteen years of age can do all except the very strenuous exercises indulged in by boys of the same age. With the onset of puberty, considerable modification of the forms of exercise given to girls is made imperative by the anatomical and physiological changes which occur at that time. The most important modifications necessary are the elimination of exercises requiring the support of the whole body by the shoulder girdle for more than an instant, the restriction of exercises involving jumping to those involving very little jarring of the body, and in general the elimination of violent exercises. The introduction of competitive athletic games in schools and colleges for girls from 1890 to 1900 was accompanied in some places by public contests between teams representing different institutions. This feature of athletics for girls has been abandoned by the leading schools and colleges because it was found to be detrimental to the best interests of education.

**GYMNASTICS, GERMAN.** — The German system embraces three distinct branches, known

as *Volksturnen*, or popular gymnastics, *Schulturnen*, or school gymnastics, and *Militärturnen*, or military gymnastics. The organization of the last two branches is maintained and controlled by the government for strictly educational purposes; the popular gymnastic societies are voluntary associations.

The names of three teachers are identified with the upbuilding of German gymnastics: Guts Muths (*qv*), 1759-1839, Jahn (*qv*), 1778-1852; and Spiess 1810-1858. Before the period covered by the activities of these men, the only physical training found in German schools was the knightly exercises in riding, fencing, vaulting, and dancing taught in the *Ritterakademien*, and instruction in running, jumping, climbing, balancing, and carrying of heavy weights, given in Basedow's school at Dessau. Salzmann (*qv*), who had been an assistant at Dessau, founded the Schnepfenthal school in 1784, and introduced the simple exercises known as the Dessau pentathlon. A year later, Guts Muths entered upon his service as a teacher at Schnepfenthal, and devoted himself to the development of a rational system of gymnastics and games. He published his *Gymnastics for the Young* in 1793, the first German manual of gymnastics, this was followed three years later by a book on plays and games. Guts Muths' aim was distinctly pedagogical; he divided physical exercises into gymnastics, manual training, and youthful plays, and defined gymnastics as "a system of exercises having bodily perfection for their aim." The success of Guts Muths' gymnastics at Schnepfenthal led to their introduction in many private and a few public schools. In 1804 Guts Muths urged upon the Prussian minister, Massow, the importance of introducing physical education into the schools. The minister replied that he proposed to make bodily training an essential part of his plan for national education, but the war with Napoleon prevented the carrying out of these plans.

The particular contribution of *Turnvater* Jahn to the German system of physical education was to make gymnastics popular through the organization of independent associations. In *Die deutsche Turnkunst*, published in 1816, Jahn describes the aims of his system of gymnastics as follows. "The turning system would reestablish the lost symmetry of human development, would connect a proper bodily training with mere exclusive intellectual cultivation, would supply the proper counteracting influence to the prevailing overrefinement, and would comprehend and influence the whole man by means of a social mode of living for the young. Every turning institution is a place for exercising the bodily powers, a school of industry in manly activity, a place of chivalrous contest, an aid to education, a protection to the health, and a public benefit. It is constantly and interchangeably a place of teaching and of learning. In an unbroken circle follow

constantly after each other direction, exemplification, instruction, independent investigation, practice, emulation, and further instruction. Thus the turners do not learn their occupation from hearsay. They have lived in and with their work, investigated it, proved it, and perfected it. It awakens all the dormant powers, and secures a self-confidence and readiness which are never found at a loss."

From 1820 to 1842, Volksturnen was prohibited by the government, gymnasia were closed, and gymnastic instruction was generally neglected in the schools. In 1842 the King gave his sanction to the proposal offered by the ministers of War, the Interior, and Education, that "bodily exercises should be acknowledged formally as a necessary and indispensable integral part of male education, and should be adopted as an agency in the education of the people." Massmann, who had been engaged in teaching gymnastics in Munich since 1827, was in 1843 called to Berlin to aid Eichorn's department in carrying into effect the plan advocated in the King's cabinet order. He had been trained in the methods of Jahn, but not being endowed with sufficient skill or energy to adapt Volksturnen to school needs, his administration, which lasted until 1850, was, on the whole, a failure.

Massmann was succeeded by Adolf Spiess, who has been called the "father of German school gymnastics" and the "founder of gymnastics for girls." He received his first instruction in gymnastics at his father's private school, where the methods of Guts Muths were followed. Later he became acquainted with Jahn and his methods. In 1830, while still a student, Spiess formed a class of boys at Giessen, and taught them "common exercises" (*Gemeinübungen*), or class drill in "standing, walking, running, and jumping." In Jahn's system the members of the class follow their foretuner. In 1833 Spiess became a teacher of history, singing, drawing, and turning in the public schools of Burgdorf, Switzerland. He removed to Basel in 1844 to take charge of the gymnastic instruction in the higher schools of that city, and in 1848 he returned to Germany, having been appointed to a high office in the department of education of the Grand Duchy of Hesse. He was successful in the work of organizing and supervising physical training in boys' and girls' schools throughout that state.

Spiess adopted the method of "class turning," which consists in the simultaneous performance by the whole class, either with or without the use of apparatus, of given exercises at the word of command, this method constitutes one of the fundamental principles in German school gymnastics. Spiess based his theory of bodily training on the laws of anatomy and physiology, and arranged his exercises in compliance with his understanding of those laws. He made use of a great variety of exercises, such as free movements, marching, jumping, climbing, and

Jahn's heavy gymnastics The free movements were often executed to music. The distinctive contribution of Spiess was to render German gymnastics systematic and scientific, and to adapt them to pedagogical purposes and methods. His principal books were *Lehre der Turnkunst* (Basel, 1840-1846), and *Turnbuch für Schulen* (Basel, 1846-1851).

The progress of gymnastic instruction in German schools was hindered by the lack of competent teachers. In 1851 the Royal Central Gymnastic Institute, with parallel courses of instruction for officers of the army and school teachers, was established in Berlin under the joint control of the ministers of War and Education, and Captain H. Rothstein, of the Prussian army, who had studied Swedish gymnastics in Stockholm, was placed at its head. In 1877 the institute was divided into two separate schools, one for army officers and the other for teachers of gymnastics in schools. Rothstein attempted to introduce Swedish gymnastics in the institute, and banished some of the most popular exercises of German gymnastics. His action led to a bitter controversy, in which prominent teachers, physicians, and professors of the Berlin University opposed him. He was finally defeated, and resigned his position in 1863.

Gymnastics constitutes an integral part of the curriculum in schools of all grades in Germany. Each class has its special time for gymnastics, just as it has special hours for arithmetic and reading. The exercises are carefully adapted to the age and sex of the pupils. The youngest pupils, from six to ten years old, engage in a great variety of simple games, easy free movements, marching, jumping, and climbing exercises, and the easier of the fundamental exercises on the gymnastic apparatus. In free movements and heavy gymnastics the exercises grow more complicated and difficult with the advancing age of the pupil. Walking tours, skating parties, and excursions into the woods are frequently made under the lead of those who teach turning. The gymnastic course for girls comprises the ordinary free gymnastics with or without hand apparatus, skipping ropes, marching, dancing, and balancing exercises, various games of ball, easy jumping, swinging, and climbing, and a few of the simplest exercises on the parallel and horizontal bars.

A description of German gymnastics as a system of physical training would be inadequate without mentioning the extensive development of games and plays, which has taken place in German schools during the last twenty-five years. Practically every school in Germany is equipped with a playground, and nearly all boys' schools have facilities for swimming. Organized and supervised play constitutes an essential part of the present system of physical training.

In the United States the German system of gymnastics has been adopted in many large

cities and German teachers appointed to direct the work. This is true of Chicago, Cleveland, Cincinnati, Indianapolis, Minneapolis, St. Louis, Philadelphia, etc. G. L. M.

#### GYMNASTICS, HYGIENE OF — See PHYSICAL TRAINING, HYGIENE OF

**HABIT — Use of Term** — The term "habit" in the various writings on the subject is used in a number of different ways. It is used by some writers to cover all of the organized responses of an organism. Such authors speak of the habits of the bee, of the ant, and of animals generally, meaning thereby the whole repertoire of reflexes, instincts, and habits. With advances in comparative psychology there should come a strict limitation in the use of the term "habit." *Habit should refer only to those motor acquisitions which have been acquired by an organism during its lifetime.* The term "mental habit" is sometimes used to refer to mental organization along any line. James, for example, speaks of perception as a "kind of habit." Such a use of the term should be avoided, since it introduces a vagueness in the expression similar to that now present in the term "memory."

**Rise of Consciousness and Rise of Habit Simultaneous** — Movement first appears in an organism in the form of reflexes, somewhat later, as growth processes take place, in the more complex form of instincts. Many of these instincts are not completely adaptive. In most organisms the reflexes and instincts are not numerous enough and complex enough to preserve the life of the organism. In such cases (and probably in no organism are the congenital responses wholly adequate) the instinctive and reflex groups must be supplemented by *habits*. Habits when perfected subserve the same function as reflexes and instincts. Angell and Dewey assume that consciousness arises at the moment reflexes and instincts break down — i.e. at the point where habit formation begins. As long as congenital responses are adequate, there is no consciousness, the moment adjustment begins, consciousness appears. Its appearance is an integral part of the formation of every habit. On the other hand, as habits are perfected and approach reflexes (so far as efficiency is concerned), consciousness tends to die away. To

speak figuratively, the focus of consciousness throughout life is always directed upon the difficult and new aspects of any adjustment

**Neural Basis of Habit.**—The simplest neural mechanism operating in any habit must consist of a receptor, a series of conductors, and an effector. But such a mechanism serves equally well for instincts as for habit. Two fundamental differences, however, appear between the two sets of mechanisms: (1) the "pathways" involved in instinct are inherited, while those in habit are acquired in ontogeny; (2) the series of conductors involved in habit probably always leads through the cortex, both in the early stages of the formation of the habit, and even in the later, perfected stage. In the case of many of the instincts, the neural arcs apparently may lie wholly infra-cortical. In the early stages of habit the cortex as a whole is unquestionably involved. It is a commonly expressed opinion, at least, that as habits become more and more automatic (as conscious oversight or attention becomes less and less necessary) the neural processes become more and more segmental in character—that the seat of neural control (as *e.g.* in the eye-hand or eye-foot reactions) passes to lower nervous centers, *e.g.* to the basal ganglia. The work of Franz has thrown some interesting light upon this question, but it is still an open one. Franz in his early experiments upon cats showed that if they were allowed to establish associations between food and the opening of problem boxes, they lost these associations if the frontal lobes were sectioned, but that they could relearn them. His more recent experiments upon primates confirms this earlier work, and adds the new point that if the association was completely formed there was no loss when the frontal lobes were sectioned. It would look as though the system of integration did change and become more circumscribed so far as the association area in the frontal lobe is concerned, as the habit became more complete. Whether the pathway could be still further shortened, so that the association areas of the cortex need not be involved at all, remains to be decided.

In psychology since Hartley's time (and more recently revived by James) we have spoken as though the nervous system was "modified" so as to respond in a highly special way to a stimulus which did not at first elicit a coordinated response. We have spoken as though an actual pathway was formed between the sense organs and the voluntary muscles, as though the nerve fibers became modified molecularly in such a way as to give passage more easily to an oft-repeated stimulus. Sherrington's conception of transverse membranes situated in the gray matter between the end of one axone and the dendrites of the next neurone (*Synapse*) throughout the pathway, is a more recent conception. These surfaces of separation "might restrain

diffusion, bank up osmotic pressure, restrict the movement of ions, accumulate electric charges, support a double electric layer, alter in shape and surface tension with changes in difference of potential, alter in difference of potential with changes of surface tension or in shape, or intervene as a membrane between dilute solutions of electrolytes of different concentration or colloidal suspensions with different signs of charge." In other words, we have at the synapses a mechanism delicate and complex enough to account for the "formation of pathways," reinforcement and inhibition of habits, etc., without supposing that there is any actual change or modification occurring in the neurone itself (the conductor) as the result of repetition of stimulus.

Habits come to preponderate over reflexes and instinctive activity in those organisms born with the least mature nervous systems. Watson and Allen's comparative experiments on the rat and the guinea pig respectively show that the rat with its immature nervous system begins to form habits (10-12 days) much later than the guinea pig (2-3 days), which is born with a relatively mature nervous system, but that the rat can form a greater number of such associations and continue to form them for a much longer time. *Plasticity* is the term used to cover the fact that an animal can *modify* its reflexes and instincts in the direction of habit. In general, the higher we ascend in the scale of animal development, the more plastic the nervous system seems to be, its culmination being in man. Yet this advance in plasticity is not continuous. Even in the rodent group we have great differences in plasticity between the rat and the guinea pig. While the chimpanzee and orang-outang stand next to man, certain other of the primates, baboon, rhesus, etc., are probably not greater in plasticity than the dog. (See PLASTICITY).

**Facilitation and Inhibition.**—The subject of facilitation and inhibition in the formation of complex habits is a topic strangely neglected in experimental psychology. We have in Sherrington and in many other neuro-physiological treatises a large amount of data on inhibition and reinforcement of the simpler neural processes. But experimental pedagogy has more or less neglected studies, *i.e.* from the standpoint of facilitation and the reverse, of the simultaneous formation of several habits, the mutual relations existing among groups of habits, etc.

On the neural side we have known for some time (thanks to the work of Exner, Mitchell and Lewis, Lombard, Bowditch and Warren, and more recently, of Sherrington and of Yerkes), that the end effect produced by any given reflex arc is dependent upon the intensity of the stimulus arousing that arc, upon the internal condition of the arc, and upon the number and temporal relations of preceding reflexes and upon the action taking place

simultaneously in other reflex groups. A sound conveyed to the ear of a chloralized rabbit increases the amplitude of the reflex movement of the foot induced by the stimulus applied to the foot a moment later. The amplitude of the movement of the knee jerk in man likewise can be diminished or increased by stimulating, *e g* some distance receptor at varying intervals before administering the electrical stimulus calling out the reflex. For a careful treatment of the neural processes, see Sherrington, *Integrative Action of the Nervous System*, pp 175 ff (reinforcement), 191 ff (inhibition), 199 ff (interference), and 36 ff (summation).

**Early Habits: the Acquisition of Motor Control** — Early habits are formed both in the child and in the animal by the trial and error process (*qv*). The start of voluntary control may best be seen in the child in its first attempts to grasp objects. There are several stages in the process, first, there must be an objective stimulus which arouses movement. Bright objects, moving objects, those making tones or noises of medium intensity, or those possessing certain pleasing contact value, in the normal child are most likely first to elicit movements. In the second place, if progress toward coordination is to be made, some one of the moving organs of the child must come into tactual motor relations with the object. The rattle which is first seen elicits a number of motor responses. Usually and in the long run the hands, being the most motile organs, are first to touch the object. Touching this object, reflexly leads to grasping, the grasping of the object then leads to new forms of stimulation, *i e* auditory and visual (of movement of object). The object is now under control, and adaptation is complete. It is supposed that a strong affective tone, intensely pleasurable in character, appears on the completion of the adaptation—upon the successful effort to control the object. It is supposed further that this affective accompaniment means on the physiological side an increased blood supply for those neuro-muscular processes which have just been active, *i e* for the group bringing about the success. Thorndike speaks of this as the “stamping-in process.” The failure of any group of muscles to bring success, on the other hand, brings about a loss in tone in those muscles, which results in their discontinuance. In other words, the neuro-muscular system bringing success is made prepotent (by some change taking place probably at the synapses).

The second trial of the child or animal shows usually, but not always, a decrease in the number of useless movements and an increased speed in the use of the muscular group which brought success on the first trial. Subsequent growth takes place through the entire elimination of all useless movements. In the perfected form the sensory impulses

aroused by the object release immediately the proper motor response.

Such command over the muscular system is finally attained that in adult life operations requiring a long series of muscular acts may be executed without the exercise of continuous voluntary control. The initiation of the first movement in the chain is usually a voluntary process. As James has well shown, this initial movement becomes the stimulus to the second, the first and second to the third, and similarly throughout the series. In other words, the “cue” to the second and succeeding acts finally may come to be kinesthetic.

**Formation of Hierarchies of Habit. Acquisition of Skill** — In the acquisition of any skillful act, as, *e g* piano playing, typewriting, sending and receiving the telegraphic code, there are displayed, in addition to the simple sensory-motor coordinations, complex or integrated groups of coordinations, which when studied in detail show an interesting history. W F Book describes five separate steps in making a single letter on the typewriter, as follows: (1) getting the copy, (2) actual spelling or thinking of each letter to be made, (3) mentally locating it on the keyboard, (4) getting the proper finger to the key, (5) again pronouncing the letter or initiating the final letter-making movements. These simple habits are short-circuited or abridged by a long, slow process until the mere sight of the letter initiates the movement for depressing the key, *i e* the letter association has been formed. Long before the process has become automatized the next higher order of habit has put in its appearance, *i e* these simple “letter habits” become integrated into “syllable habits,” then into easy “word habits,” then into complex word habits, into easy “phrase habits,” etc., until finally the expert stage is reached, where the word and phrase habits have become so perfected that the writing is absolutely continuous. In this process of acquiring skill, simple habits are not first mastered and then the next higher order, etc., until the expert stage is reached. All orders of habits “make gains simultaneously, but not equally” (Bryan and Harter, *Psych Rev*, Vol VI, 1899, pp 346-375). Book compares the development of the different orders of habit to the march of a flock of sheep, the whole flock moves forward, now fast, now slow, but any particular animal may push ahead at this moment and lag behind at the next.

**Breathing Places and Plateaus** — The onward movement of the group of habits as a whole is often checked. There are daily fluctuations, due in part to mood, fatigue, and the actual forgetting between one day's practice and the next, especially when new and higher orders of habits are just appearing (see Book on “warning-up process”). In addition to these easily understood fluctuations there are

longer and more serious breaks in the process, lasting from six to eight days (Book), and still longer periods called plateaus, occurring at critical stages in the learning process and enduring for a much longer time than the "breathing places" (thirty-three days in one case mentioned by Book). These plateaus (including the "breathing places" under this heading) appear in the work of Bryan and Harter (telegraph sending and receiving), Swift (tossing and catching balls), and Book (typewriting). Bryan and Harter suppose that these plateaus appear when the lower order habits are approaching their maximum of development, but are not sufficiently automatic for use as elements in the higher order habits. For these investigators they are necessary periods of "incubation," where elementary habits are making substantial gains preparatory to their organization into higher order of habits. Book objects to this theory of plateaus on the ground that there is not a sufficient time sequence in the development of the different orders of habits. He separates the breathing places from the plateaus. The breathing places are due to irregular lapses in attention. A bad day's work may dampen the learner's ardor for several days. Plateaus, on the other hand, while not appearing in all of Book's curves, occur, when at all, at critical stages in the learning process. They are, according to Book (a) "Resting places in the learner's interest and effort, or (b) 'break-down' stages caused by excessive effort wrongly applied."

As a matter of fact, a complete analysis of these breaks in the learning process cannot yet be given. Nearly all of the investigators have chosen habits which are too complex for complete analysis. From the standpoint of neural control, there seems to be no conceivable reason why a learning curve should show fluctuations other than those reflecting the general bodily condition and those due to changes in metabolism.

**Transfer of Habit: Cross-Education** -- It is apparently firmly established that the exercise of any one muscular organ of the body will improve the bilaterally symmetrical organ. Volkman found that practicing the left arm in discrimination produced a very marked improvement in the right without any practice in the latter. Similar experiments show that practice upon the dynamometer with either hand will improve the strength of grip in the other (Scripture, Downs, *et al.*). Similarly Davis found that improvement in the quickness of the tapping with the right great toe was accompanied by 151 per cent improvement in the left foot, 100 per cent as much in the right hand and 83 per cent in the left hand. Woodworth has made experiments with similar results upon the accuracy of hitting a dot. Davis's conclusions that the effects of exercise may be transferred to a greater or lesser

degree from the parts practiced to other parts of the body, and that the transference is greatest to symmetrical and closely related parts, is firmly established, but the interpretation of the facts is not very clear. The whole question is more or less bound up with that of the effects of training upon memory. (See MEMORY.) Thorndike, with his theory of "identical elements" in memory transfer, attempts with some success to extend his theory to cross education, *e.g.* holding that Woodworth's transfer obtained in striking at a dot with the left hand is due largely to the fact that the practice with the left hand trained the eye, and that this training is largely responsible for the improvement noted in the right (unpracticed) hand. The more recent and thorough work of Ebert and Meumann tends to establish the fact against James, and to some extent against Thorndike as well, that rote memory can be improved by practice. The position that such effects were due to common elements and to common modes of attack, better use of attention, elimination of useless methods of attack, increase of interest in problem, etc., is still a tenable one. It must be said, however, that Ebert and Meumann themselves hold that in addition to these factors there is a training of some common memory capacity.

**Automatism and Allied Phenomena** -- In hypnosis, in certain functional nervous diseases, and in sleep walking, we meet with automatic reactions of various kinds. They may show themselves in the form of word repetitions, *echolalia*, gesture repetitions, *echopraxia* (in hypnosis, *katatonia*, etc.), and in stereotypy. Stereotypy may take different forms, *e.g.* we may have a stereotypy of attitude, of movement, or of language (*verbigitation*). In these cases we often see patients maintaining uncomfortable attitudes for hours, others will walk for long distances, taking alternately three steps forward and two backward, others will repeat phrases or verses indefinitely. Such phenomena belong to the field of psychiatry rather than to that of psychology and education. In normal individuals such phenomena are occasionally met in fits of abstraction and in sleep.

**Social and Pedagogical Implications of Habit** -- The ideal training of a human being would give him the ability to react adequately and rapidly and with a minimum of fatigue to any individual or social situation. In our complex civilization, which is ever changing in its point of stress, which is ever presenting new problems, an organism must automatize as many adjustments as possible, and as easily and as rapidly as possible in order to leave the mind free to meet the point of stress. The early formation of right personal habits has been insisted upon in all writings upon habits. Probably the necessity of forming habits which are not immediately utilizable

has not been sufficiently insisted upon. During adolescence there is, especially if there is a bad inheritance, a period when many new and strange demands are made upon the nervous system. At times it breaks down under the strain. Good personal habits — those relating to temperance, control of the sex impulses, the right use of money, respect due to other members of society, etc., serve oftentimes to carry the individual with poor inheritance safely over the periods of conflict. Often when this faulty inheritance is present it is augmented by carelessness in the formation of the early habits (in paranoia, *e g* we find carelessness in the use of money, extravagances, etc., in many forms starting very early in life. The implication is that such tendencies might be checked if noted early enough). Much has been and is still being done in the case of functional nervous diseases by the process of reeducation. In regard to the second point, — forcing the youth to form habits not immediately utilizable, — possibly enough has not been said. Normal development in certain cases ceases after a fixed low level of efficiency has been attained. Such subjects either have to be carried through life by other members of society, or else they must be trained to take a more modest but independent place in life. Manual training for the male and similar training for the female in household work, sewing, millinery, etc., is of the utmost necessity. Even though normal development continues, these habits in times of financial reverses are of the utmost advantage to their possessors. J. B. W.

**HACKNEY COLLEGE.** — See LONDON, UNIVERSITY OF.

**HADLEY, JAMES** (1821–1872) — Textbook author and college professor, was educated at Fairfield Academy and graduated at Yale College in 1842. He was many years professor of Greek at Yale, and was the author of a widely used series of Greek texts.

W. S. M.

**HAGAR, DANIEL BARNARD** (1820–1896) — Normal school principal, was born at Newton, Mass., on Apr. 22, 1820. He was educated in the public schools of Newton and graduated at Union College in 1843. He was for several years principal of academies in New York, and later was principal of the high school at Jamaica Plain, Mass. From 1865 to 1896 he was principal of the State Normal School at Salem, Mass. He issued the call for the organization of the National Teachers' Association (*q.v.*), was one of the organizers of the Massachusetts Teachers' Association, and for some years one of the editors of the *Massachusetts Teacher*. He also wrote numerous papers on normal school education.

**HAILEYBURY COLLEGE** — See GRAMMAR SCHOOLS, ENGLISH, COLLEGE, ENGLISH, PUBLIC SCHOOLS.

**HAITI, EDUCATION IN** — The Republic of Haiti occupies the western part of the island of Haiti, the second in size of the West Indies. The original inhabitants were practically exterminated in contests with the Spanish invaders, who eventually gained peaceful possession of a depopulated island. It was repopulated by African slaves, first imported in 1517. The Spaniards gradually deserted the island for the more attractive regions of the American continent. French and English adventurers formed a settlement on the northern shore,

which was recognized as a department of France in 1714, to which country that portion of the island had been ceded by the Treaty of Ryswick, 1697. The uprising of the negroes in 1791, the heroic leadership of Toussaint l'Ouverture, and the final surrender of the island to France, in 1795, are memorable episodes in its early history. After a long period of struggle and uncertain destinies, the Dominican Republic was proclaimed in 1824, and in 1858 the Republic of Haiti was established. This division of the island covers an area of about 10,200 square miles and has a present population estimated at 2,029,000, of whom nine tenths are negroes and the remainder, save two or three hundred Europeans, are mulattoes.

For purposes of local administration the republic is divided into five departments, comprising eighty-six communes. The people are Roman Catholics, and society retains the distinctions of the old régime in France, the upper class possessing wealth and refinement, in striking contrast with the ignorant masses. The leaders of the republic have professed great regard for education, and their public utterances on this subject reflect the theories and sentiments of the leaders of the French Revolution, but with few exceptions, among whom should be named in particular President Fabre Geffrard, they have been theorists merely, or prevented by repeated revolutions from giving effect to their purposes.

Public instruction was represented in the government of the new republic by a cabinet officer, and the country was divided into fourteen districts, to each of which was assigned a government inspector of schools and higher institutions. In 1860, or two years after the republic was proclaimed, a law was passed providing that public instruction should be gratuitous, and the establishment of primary schools obligatory upon local authorities. Through the efforts of the Minister of Public Instruction, M. Elie Dubois, schools were established in the principal cities, and they have been maintained to the present day. In the country districts very little progress has been made, the fitful endeavors in this direction having been constantly interrupted by political commotions. At present there are about 480 public primary schools, of which number 275 (122 for boys, 153 for girls) are in the cities. The total includes 39 schools for boys in charge of Christian Brothers (*q.v.*), and more than 50 schools for girls in charge of sisterhoods. Schools established by the teaching orders of the Church are adopted as public schools and receive appropriations from the public treasury. In fact, to the teaching orders must be credited nearly all the progress in education thus far realized in the island.

The influence of French precedents is seen in the establishment of schools in which training for the industrial arts is combined with general

education. The earliest institution of this sort in Haiti was the *Maison Centrale*, created in 1849 during the imperial rule of Souleouque, whose adventurous career reached its climax in 1846, when he was acclaimed Emperor under the title of Faustin I. The *Maison Centrale*, or School of Arts and Trades, is a government institution, occupying a commodious site at Port-au-Prince, and having accommodation for 150 boarding pupils. The course of instruction includes academic studies, technical branches, religion, music, and military tactics. The school is equipped with fourteen workshops for wood and metal work, blacksmithing, carriage manufacture, etc., but still needs provision for some of the pressing demands of Haiti in industry. A second technical school, *École libre professionnelle*, was established at Port-au-Prince under private auspices in 1892, but through lack of financial support was soon discontinued. There are two orphanages for girls, one at Port-au-Prince and the other at Cayes, both managed by sisterhoods, but subventioned by the government. The former and more important of the two, the *Orphelinat de la Madeleine*, was founded Feb. 18, 1893, by the Mother Superior, Eustochie, of the sisters of St. Joseph of Cluny. The institution receives an annual grant from the State of 444 gourdes (\$429). The instruction includes, besides the elementary branches, housekeeping and household arts, sewing and cutting, embroidery, lace making, etc.

For the secondary education of boys there are in the six principal cities public lycées which follow official programs. A commission appointed in 1893 to advise as to desirable modification in the plan of study recommended changes in favor of modern subjects, especially the scientific studies that prepare for the medical profession and for the technical arts. There are a number of business colleges for young men and several excellent secondary schools in charge of the teaching orders, also a college supported by the Wesleyan mission.

Higher education is represented by a national school of medicine and pharmacy, a school of maternity, and a school of law, all at Port-au-Prince, and by private schools of law in other cities, which receive grants from the public treasury. The national school of applied sciences at Port-au-Prince is equipped with a bacteriological laboratory at which important investigations are conducted. The fine arts are promoted by the national school of drawing and painting, also at the capital.

A select number of youths are sent every year by the government to study in Europe or in the United States; but while opportunities are thus provided for an élite circle, the low state of the masses is recognized and deplored. An earnest effort at reform was begun in 1910 by the passage of a compulsory education law with penalties for its violation, but subsequent revolutions have prevented further progress in

respect to general education, and have interrupted plans for developing technical education, more especially as related to agriculture. The annual budget for public instruction is about 4,000,000 francs (\$800,000). A. T. S.

**HAKLUYT, RICHARD** (?1552–1616) — The great historian of Elizabethan travels, under the title of the *Principal Navigations, Voyages, Traffiques and Discoveries of the English Nation within the compass of these 1600 years* (published 1589), was educated at Westminster School, where Honter's *Cosmographia* was taught. In 1570 Hakluyt was chosen student of Christ Church, Oxford, and took his M.A. in 1577, and became a preacher. In the Epistle Dedicatory of his *Principal Navigations* he narrates how his cousin Richard Hakluyt in his chambers at the Middle Temple had instructed him in certain books of Cosmography, with a universal map, pointing with his wand to all the known seas, gulfs, bays, straits, capes, rivers, empires, etc., and giving him full geographical information about them. When he went to Christ Church, he continued these studies, reading whatever he could find extant in the Greek, Latin, Italian, Spanish, Portuguese, French, and English languages. "In my public lectures," he says, "I was the first that produced and shewed both the old imperfectly composed and the new lately reformed Maps, Globes, Spheres, and other instruments of this art for demonstration in the common schools, to the singular pleasure and general contentment of my auditory." On Apr. 1, 1584, Hakluyt wrote a letter to Sir Francis Walsingham, directing the foundation of a lectureship in mathematics and another on the art of Navigation in London in or about Ratchiff, at a yearly stipend of £50 each. He cites the case of the mathematics lectureship secured at Paris by Peter Ramus (*qv*). Though Hakluyt was not successful in getting a lectureship in navigation established, the teaching of the subject in mathematical schools (principally private) in the seventeenth century became a settled practice. **HALES, ALEXANDER OF** (d. 1245) — The first great schoolman, exercising a powerful influence over his successors, who made the thirteenth century the golden age of Scholasticism. He was born and educated at Hales in England, and became a Franciscan friar. He was one of the most famous professors at the University of Paris, and won for himself the titles of *Doctor Inefragabilis*, *Doctor Doctorum*, *Theologorum Monarchia*, and *Fons Vita*. Bonaventure was one of his pupils, and Thomas Aquinas and Duns Scotus were profoundly influenced by him. Writing just after the recovery of the works of Aristotle, he was the first to bring the Aristotelian ethics and philosophy to bear upon the Christian system. While his psychology was Aristotelian in its general trend, it followed the traditional Augustinian views of the soul and its faculties. His most important contribution to philosophy was the development of the scholastic method (*qv*) and its application to the discussion of theological problems. This method, which controlled the thought of several succeeding generations, and is still dominant in Roman Catholic theology, was fully developed in his vast *Summa Theologiae*, which was written at the request of Pope Innocent IV and printed at Nuremberg in 1482, and served as the model for the great summists of the next generation. His chief contributions to Theology were the doctrines of the Treasury of Merits and the Indelibility of the Sacraments, which have ever since held so prominent a place in the teaching and practice of the Roman Catholic Church. **HALL or HOSTEL** (*Aula, Hospitium, Pædagogium*). — Originally a house (or even a single room) tenanted by a group of university students in common. In some cases these would perhaps be boarders with a master, we find early university statutes directed against masters canvassing on the one hand for pupils among the freshmen, and, on the other hand, outbidding each other for houses. In other instances the principal was originally one of the scholars, or even a townsman, who made himself responsible for the rent, etc. In any case the halls were at first startlingly democratic; principals were elected and statutes were framed by the consent of all the students; and this custom influenced the earliest colleges, which were in fact only endowed *hospitia*. An instance of the transition between a hall and a college may be seen in the foundation of St-Honoré at Paris. This was "a certain house, to be furnished with thirteen beds for the use of poor scholars" under the wardenship of one of the Canons of the Church of St-Honoré, who was however to be removed if the students showed just cause of complaint against his rule (Denifle, *Chart Univ Paris* 1 68). The earlier colleges were in fact generally styled "House" or "Hall," a fact which may best be illustrated by enumerating the first twelve Cambridge endowments in order of their foundation. These are Peterhouse (1284), Michaelhouse (1324), Clare Hall (1326), King's Hall (1337), Pembroke Hall (1347), Gonville Hall (1348), Trinity Hall (1350), Corpus Christi College (1352), King's College (1441), Queen's College (1448), St Catharine's Hall (1475), Jesus College (1496). The great foundation of Trinity (1546) absorbed two older colleges (Michaelhouse and King's Hall) and seven hostels, of which one (Garret Hostel) retains its name to the present day. Dr. Rashdall has traced the steps by which the halls passed from simple lodging houses into officially recognized and controlled communities. University control may be said to have

## HALL

begun with the thirteenth-century legislation which enacted that a house once tenanted by students might thenceforth be let to no outsider so long as there were still students to hire it. Then (about the beginning of the fifteenth century) the authorities attempted to enforce residence in colleges or halls upon all but the richest and poorest students, and, at the same time, to enforce stricter rules within these buildings. The principalships were restricted to masters, and in many other ways collegiate reacted upon aularian discipline, yet these reforms worked so slowly that at Paris, as late as 1486-1487, "certain women kept halls and colleges," as in later times the Dames' Houses flourished at Eton. We must therefore look upon the original meaning of "Hall" as a rather elastic term. Among Cambridge colleges, Clare and St Catharine's kept the title until quite recent times, Trinity Hall keeps it still to avoid confusion with Trinity College. At Oxford, not only the title, but the thing still survives in St Edmund's Hall, endowed as early as 1260, but never formally incorporated, and existing since 1557 in partial dependence upon Queen's College, others were merged into colleges during the nineteenth century. A few modern halls have been founded both at Oxford and at Cambridge for certain groups of non-collegiate students, mostly on a denominational religious basis. The term "hostel system" has been applied in modern times to the more economical arrangements in force at the recent foundations of Keble College, Oxford, and Selwyn College, Cambridge, where the students have all meals in common, and in other ways conform more closely to the collectivist economy of medieval halls and colleges. G G C.

**HALL, ARETHUSA** (1802-1880) — Leader in the movement for the higher education of women, privately educated. She was principal of academies at Greenland, N H., and Haverhill, Mass (1826-1849). At the latter academy she was the instructor of the poet John G Whittier. She was also engaged in secondary school work at the Brooklyn Female Academy (now Packer Institute) and the Brooklyn Heights Seminary (1849-1860). She wrote *Manual of Morals* (1849), *Literary Reader* (1850), and papers on the higher education of women. W. S. M.

See WOMEN, EDUCATION OF.

**HALL, BAYARD RUST** (1798-1869) — Educational writer and principal of secondary schools, was graduated from Union College in 1820 and Princeton Theological Seminary in 1823. He was president of the College of Indiana (which subsequently became Indiana University) at Bloomington from 1823 to 1831, and principal of academies in New York, Pennsylvania, and New Jersey from 1831 to 1846. His educational publications include a *Latin Grammar* (1828), *The New Purchase* (a satire on the higher educational institutions in the Middle West, 1843), *Teaching a Science* (1848), and *The Teacher Taught* (1852) W. S. M.

**HALL, JOHN** (1627-1656) — An English scholar, wrote at the age of twenty-two years, *An Humble Motion to the Parliament of England concerning the Advancement of Learning and Reformation in the Universities*. He was educated at Durham School and studied at St. John's College, Cambridge. He removed to London in 1647, and entered at Gray's Inn. The *Humble Motion* contains a vigorous onslaught on the university studies and teaching of the time, written, as the title shows, under the inspiration of Bacon's writings. He complains of the abuse of the endowments of the university. The revenues might be devoted to the establishment of more professorships and fewer fellowships. He says, speaking of Cambridge, that there are only professorships for the three principal faculties, and "these but lazily read, and are carelessly followed." He complains that no chemistry is studied, an early reference to the subject by this name. He deprecates the lack of "quick or dead anatomies, or ocular demonstration of herbs." Nor is there any "manual demonstration of mathematical theorems or instruments." He suggests "a calculation and amendment of the epochs of time." He suggests that the needed reformation of the universities can be brought about by reducing the "friar-like" list of fellowships, so that it only includes working fellows of different kinds. Money thus saved could be applied to experiments and inventions, etc. Improving on Humphrey Gilbert (*q v*) he suggests that two (instead of one) new books could go to the public library, and that copies of foreign books sold in England should also be required. Antiquities, *e g* medals, statues, ancient rings, etc., taken from confiscated estates, should go to the public museums, and foreign scholars should be honored. Like Comenius, he is an advocate of realistic instruction in the school. In short, his University demands are the further development of mathematics, the determined investigation of natural science and cataloguing of results, and the drawing up of a synopsis of medicine. Hall is said to have had a pension from the Commonwealth authorities equivalent to £350 a year of present money, and Thomas Hobbes the philosopher said of

him: "No man had ever done so great things at his age." F. W.

**HALL, SAMUEL READ** (1795-1877) — One of the earliest organizers of American institutions for the training of teachers, was born at Croydon, N.H., on Oct. 27, 1795. He was educated in the district schools and at Kimball Academy, Meriden, N.H. For ten years he was a teacher in the district schools, and in 1823 he organized a seminary for the training of teachers at Concord, Vt. The seminary was later moved to Andover, Mass., and subsequently to Plymouth, N.H. During the seventeen years (1823-1840) that Mr. Hall conducted his teachers' seminaries, the first of their kind in the United States, he was active in agitating the cause of professional education. His *Lectures on School-Keeping* (1829) and his *Lectures on Female Education* (1832) were important contributions to the scientific study of education during the early period. Hall was one of the founders of the American Institute of Instruction (*q v*), and he is reported to have made the first use of blackboards (*q v*) in the United States. The late Henry Barnard is authority for the statement that Hall used blackboards in the district schools that he taught prior to 1815, and extensive use was made of blackboards in the teachers' seminaries that he conducted between 1823 and 1840. Besides the two educational books already referred to, Hall was the author of numerous textbooks, including *The Child's Assistant* (1827), *Geography for Children* (1832), *School History of the United States* (1832), and *School Arithmetic* (1836) W. S. M.

See EDUCATION, ACADEMIC STUDY OF

**HALL, THOMAS** (1610-1665) — Minister and schoolmaster — a pedagogical follower of John Brinsley (*q v*). He was educated at the King's School, Worcester, where Henry Bright was schoolmaster, from 1624 to 1629 he was at Oxford. He returned to Worcestershire and taught a "private school at the Chapels belonging to King's Norton." He became curate of King's Norton and master of the free grammar school at the same place. In his school work, some persons of quality sent their sons "to table (board) in the house with him," and many of his scholars proved able ministers. He contributed to the library of the Free School at Birmingham, and at King's Norton he gave his study of books, on condition that the parish built a library house for them.

The classical school textbooks written by Hall are. (1) *Wisdom's Conquest — or An Explanation and Grammatical Translation of the*

13th book of *Ovid's Metamorphosis* (1651); (2) *Phaeton's Folly or the downfall of Pride. Being a Translation of the 2nd Book of Ovid's Metamorphosis, paraphrastically and Grammatically* (together with Flowers, Phrases, Rhetoric, Etymologies) (1655)

Hall further wrote the *Vindiciæ Litterarum, the Schools Guarded* (1654), in which he attacked the position of the Anabaptists, who argued according to Hall that the arts and sciences are "idols, anti-christian, the smoke of the bottomless pit, filth, froth, dung, needless and useless for the right understanding of the Scripture. The Spirit alone was sufficient without the human help of learning." Hall therefore undertakes to prove the excellency and usefulness of arts, sciences, languages, and history and all sorts of human learning in subordination to divinity and preparation for the ministry. Hall's defense of learning is cast in logical form. It is followed by *Centuria Sacra*, a hundred rules for expounding the Scriptures and a Scriptural rhetoric, containing a compendium of all the most material tropes and figures in the Scriptures. In the same volume is contained the *Histriomastix*, or a whip for Webster — an examination of John Webster's (*qv*) *Examen of Academies*, which Hall calls "delusive," and claims to show the sophistry of Webster's "new-found light," which Hall thinks tends to the subversion of universities, philosophers, physicians, magistrates, ministers. Hall also wrote books on the *Loathsomeness of Long Hair*, 1654, and the *Downfall of May-Games*, 1660 F W.

**HALLE.** — See FRANCKE, AUGUST HERMANN; GERMANY, EDUCATION IN, under UNIVERSITIES, THOMASIIUS, CHRISTIAN, WOLFF, CHRISTIAN.

**HALLE, THE ROYAL FREDERICK UNIVERSITY OF** — This institution was established in 1694, the University of Wittenberg (*qv*), established in 1502, being incorporated with it in 1817, this explains the official title, *Vereinigte Friedrichs-Universität Halle-Wittenberg*. The plan of founding a seat of higher learning at Halle goes back to the Elector Frederick III of Brandenburg, who was desirous of maintaining a university for the newly acquired duchies of Halberstadt and Magdeburg, thereby removing the existing dependence upon the nearby Saxon university of Leipzig, he was furthermore anxious to possess another Lutheran citadel of learning besides the somewhat remotely situated University of Königsberg. The celebrated jurist Thomasius (*qv*), whose advanced ideas had led to his dismissal by the conservative University of Leipzig, transferred his activities to the city of Halle in the late eighties of the seventeenth century, and was followed a few years later by the theologian, August Hermann Francke (*qv*), who had been forced to leave the same institution. The imperial sanction for the establishment of a regular university was not secured, however,

until 1693 (Oct. 19), the formal opening taking place on July 12 of the following year. From the beginning an institution of four faculties was planned, the theological faculty representing more liberal Lutheran tendencies than prevailed at Wittenberg and at Leipzig. Indeed, the entire spirit of the new institution was *modern*, in consequence of which it has been styled by Paulsen the first modern university. Thomasius had evoked considerable opposition at Leipzig not only by announcing, but actually delivering his lectures in the German language, at Halle he was free to do as he chose, and as a result of his example German gradually displaced Latin as the vehicle of expression in university lectures. The theological faculty was for many years the most important of the university, pietistic tendencies prevailing, and during the third and fourth decades of the last century was the most renowned in Germany. The medical faculty did not attain importance until the beginning of the nineteenth century, several clinics having been established at the end of the previous century, at which time the natural sciences were still included in this faculty. The faculty of philosophy had secured wide renown at the beginning of the eighteenth century, largely through the influence of Christian Wolff, professor of mathematics and philosophy, who was dismissed for his radical applications of philosophy to theology by King Frederick William I of Prussia, but reinstated by Frederick the Great, and again at the close of the century through Friedrich August Wolf, the philologist, who organized a philological seminar in 1787, and who was largely instrumental in divorcing this discipline from theology, upon which it had been dependent. Another prominent name connected with this faculty is that of the philosopher Eduard Erdmann, whose connection with Halle covered a span of sixty years (1836-1896). In the course of the nineteenth century various scientific institutes (physical, chemical, biological, etc.) were established, and in 1863 the best equipped agricultural institute in Germany was organized as an integral part of the university, being included under the faculty of philosophy. The political science seminar (1872) contains an excellent collection of statistical material, and has been publishing a valuable series of contributions since 1877. The library is housed in a modern building (1882), and contains about 250,000 volumes and almost 1000 manuscripts. Connected with the University Library is the Hungarian National Library, founded in Wittenberg in 1725, and containing over 100 manuscripts and over 4000 volumes of Hungaria and old Wittenberg theological literature. The university also possesses an archaeological museum, containing a numismatic collection and a collection of engravings. The annual budget amounts to approximately half a million dollars. During the first half of the eighteenth century Halle attracted more stu-

dents than any other German university with the single exception of Jena, but toward the end of the century it was passed by Leipzig, although it had grown larger than Jena in the meantime. During the winter semester of 1911-1912 its 3112 students were distributed as follows: Theology 378, law 389, medicine 356, philosophy 1572, auditors 233, more than half of the total number of matriculated students being enrolled in the faculty of philosophy. The teaching staff consists of about 100 professors and 60 docents.

**HALLUCINATION.**—A perception that does not originate from a stimulus from the world external to the body. There is no psychological distinction between hallucinations, illusion (*q v*), and perceptions (*q v*), for all are interpretations of sensory data. The distinction is sometimes made that perceptions have a sensory basis, and the interpretations from the sensory data are like those of most people, that illusions are wrong interpretations of sensory stimuli, while hallucinations have no external object corresponding to the stimulus, and that the interpretations of the mental sensory data are necessarily erroneous. The normal perceptions and illusions may therefore be called exogenous in origin, and the hallucinations are endogenous. This differentiation, however, will not hold in all cases, and there is no such sharp dividing line between perceptions, illusions, and hallucinations as is indicated by this definition. That hallucinations are abnormal, that perceptions are normal, and that illusions may be partly normal and partly abnormal is another distinction that has been drawn, but this is only partly true. Hallucinations are found to a great extent in abnormal people, but they are of almost constant occurrence in normal individuals in a certain form (in the condition of dreaming).

The qualitative characteristics of hallucinations are the same as those of perceptions. They have the subjective element of reality, they have color, form, depth, tone, and emotional effect. All these qualities are similar to those in perception of so-called normal character. We may say, therefore, that an hallucination is a perception most often due to the activity of the central nervous apparatus without the intervention of the peripheral organs, and commonly found in abnormal mental conditions.

All kinds of hallucinations may be present at the same time, *e g.* that of an animal (visual),

moving (visuo-motor), of horrible color (visual), giving forth obnoxious fumes (olfactory), that of poison (organic?), and bellowing loudly (auditory); that of being transported through the air (organic), of having wings grow (skin and organic), of seeing (visual) and talking (auditory and motor) with angels.

The most typical condition in which hallucinations are found is that of delirium, in which condition the hallucinations are sometimes the only abnormal phenomena. All toxic states in their acute forms are accompanied by hallucinations, and the diagnosis is sometimes made, other information being lacking, from the character of these perceptions. In dementia precox hallucinations are common, and they lead to the abnormal impulsive actions so characteristic of this form of mental disease. In epilepsy, the auras may be considered as hallucinations, and the confusional states following an epileptic attack are often made up of hallucinations of hearing, sight, and the organic senses. In mania, hallucinations are occasionally met with, and in paranoia they form the foundation on which the subsequent structure of delusions of persecution and ideas of grandeur is built.

The presence of hallucinations usually indicates a grave condition, although it must be remembered that the accumulation of cerumen in the ear, the presence of a catarrh or of polypi in the nose, decayed teeth, and injuries to or disease of the eye may lead to the formation of hallucinations of the appropriate sensory character. The hallucinations of peripheral origin are usually of a vague type, but if unattended to they may lead to central, *i e* cerebral, disturbances and become definite. It is generally believed that constant stimulation eventually leads to lack of attention to the sensation, but this is not always true, for we find that the constant buzzing sounds from ear affections often lead to an exaggeration of the mental character of the sensations, owing to the abnormal degree of attention being given to them, and there may result an elaboration of the sensation into a complex of a fixed character. It is, therefore, of importance that at the first sign of an abnormal sensation (hallucination) a careful examination of the sense organ be made, for the treatment of a bad physiological condition in the early stages will stop the vague hallucination and prevent the formation of a more definite one.

**HAMBURG, FREE TOWN OF, EDUCATION IN.**—See GERMANY, EDUCATION IN.

**HAMERTON, PHILIP GILBERT** (1834-1894). — English art critic, etcher, and essayist; born near Oldham in Lancashire, where he was educated at school and privately. A great part of his life he spent in France. After devoting himself for some time to painting and sketching without much success, he turned to art criticism and writing, and contributed much to spreading a knowledge of art among the public and in popularizing etchings. His best known work is the *Intellectual Life* (1873), a collection of essays in the form of letters, marked by clear, simple style, if not by a remarkable depth of thought. The thesis which Hamerton sets up is that "intellectual living is not so much an accomplishment as a state or condition of the mind in which it seeks earnestly for the highest and purest truth." In the section of the work which is devoted to education there is an insistence on the *non multa sed multum*. Modern education attempts to cover too many subjects, with the accompanying scattering of interest, lack of mastery, absence of concentration, and pressure. Hence he approves of the old and somewhat restricted curriculum, of few subjects, but thoroughly cultivated, and of a system which would now be called elective, namely the granting of certificates of competence for ability in any subject rather than insisting on a definite course concluding in a university degree. "The only hope for us is to make a selection from the attempts of our too heavily burdened youth, and in those selected studies to emulate in after-life the thoroughness of our forefathers."

**HAMILTON COLLEGE, CLINTON, N. Y.**

— An institution which developed out of the Hamilton Oneida Academy, established by Samuel Kirkland, a missionary of great influence among the Oneida Indians, who had been a pupil at Dr. Wheelock's Indian School at Lebanon (see DARTMOUTH COLLEGE). The academy was chartered in 1793, and among its trustees was Alexander Hamilton. John Niles, a Yale graduate, was the first principal when work was begun in 1798. In 1812 it was decided to extend the scope and influence of the institution, and funds were raised for a college through the efforts of Rev. Caleb Alexander, a grant was also obtained from the legislature. Hamilton College was chartered in 1812, and it was proposed to begin with professors of chemistry and mineralogy, surgery, and anatomy, the institutes of medicine, and obstetrics. Nothing became of the suggested medical chairs, however, for some time. The first president was Rev. Dr. Azel Backus, a graduate of Yale (1812-1817). The number of students rose rapidly, and buildings were added at the

cost, however, of the reserve fund, so that by 1835 a second permanent fund was established. Under President Simeon North (1839-1857) progress was again very well marked; buildings were improved and added to; and new subjects were introduced, including geology and mineralogy, elocution and rhetoric, law, political economy and history, moral philosophy and religious instruction, French and German. The succeeding presidents have been Dr. Samuel Ware Fisher (1858-1866), Dr. Samuel Gilman Brown (1868-1881), Dr. Henry Darling (1881-1891). Hamilton College has had a number of distinguished scholars on its faculty, and on its roll of alumni are to be found the names of many who have achieved distinction in the Christian ministry and in all fields of public life.

The college is well situated in the midst of beautiful scenery, with a campus of ninety acres, and comprises sixteen buildings used for recitation and other purposes. The entrance requirements are equivalent to fifteen units. Two courses, classical and Latin scientific, are offered, leading to the degrees of A B, Ph B, and B S. The student enrollment in 1911-1912 was 190. Provision is made to receive the students in dormitories and fraternity houses. There is a faculty of twenty members. Melancthon Woolsey Stryker, D D, LL D, is the president.

**HAMILTON COLLEGE, LEXINGTON, KY**

— An institution for the education of young women, established in 1869. College preparatory, collegiate, music, art, and expression courses are offered. Two years of college work are offered, for which credit is given at the Transylvania University (qv). There is a faculty of twenty-five members.

**HAMILTON, JAMES** (1769-1829) — In-

ventor of a new method of learning languages — the Hamiltonian System. He was born in London, but spent most of his time in Europe as a merchant. He studied French, German, Italian, Latin, and Greek. A reversal of fortune compelled him to resort to teaching languages. His system consisted in putting foreign textbooks with literal interlinear translations into the hands of his pupils and giving them a vocabulary before he taught grammar. He made an experiment in London on a number of poor boys placed under his charge by an English member of Parliament for six months, at the end of which they could translate the Gospel of St. John and Cæsar's *Commentaries*. Hamilton taught languages very successfully (1815-1823) in most of the large Eastern towns in America, as well as Montreal and Quebec. On his return to England he taught in London and many other towns. He was several times attacked as a charlatan and impostor, but although he certainly employed methods of advertising which were not above suspicion,

there is no reason to believe that he was not honest. He published many keys, including the Gospels of St. Matthew and St. John in Greek; Gospel of St. John, *Æsop's Fables*, Eutropius, *Phædrus* in Latin, Gospel of St. John, Perrin's *Fables*, in French, Campe's *Robinson Crusoe* in German, Gospel of St. John in Italian. His system he describes in *History, Principles, Practice and Results* . . . of the *Hamiltonian System* (Manchester, 1829).

SMITH, SYDNEY *Essays Social and Political*. (London, n. d.)

**HAMILTON, SIR WILLIAM** (1788-1856). — A leader in the school of Scottish metaphysics. After some schooling in Scotland and two years in London, Sir William went in 1807 as a Snell exhibitioner to Balliol College, Oxford, where he pursued his studies zealously, though with some independence, devoting himself chiefly to the study of Aristotle and the classics. Graduating with honors in 1810, he became a member of the Scottish bar, and took up his residence in Edinburgh. He was not markedly active or successful in his chosen profession, chiefly because his life was mainly that of a student, he devoted himself to researches of all kinds, unbroken except for occasional excursions into the field of practical politics and social reform. In 1820 he was an unsuccessful candidate for the chair of moral philosophy in the University of Edinburgh, where, however, in 1836, he was appointed to the professorship of logic and metaphysics, a position which he held till his death. Meanwhile, in 1829, his career as a philosophical writer began with the appearance in the *Edinburgh Review* of some articles on *The Philosophy of the Unconditioned*. His edition of the works of Reid appeared in 1846, that of Stewart in 1855.

His philosophy was not systematically developed, but its main points are clear enough. The central point is his view of consciousness, which he analyzed under three aspects. (1) As it is in itself. In this sense consciousness is noumenal and is another name for immediate or intuitive knowledge. (2) As divided into the three groups, cognition, feeling, and conation. Consciousness is recognition of its own acts and affections. But it is only cognition which has received at his hands adequate treatment. The laws of cognitive activity he has developed with remarkable precision. His doctrine of perception was influenced by both Hume and Kant, and usually teaches that matter is in itself unknown, and that, so far as it is perceived, it is perceived only in its relations to the perceiving mind. (3) Consciousness is called conditioned, and assumes the form of common sense. The facts here he classified into truths of perception and truths of reason, both of which are alike inscrutable in their essence and

therefore inexplicable. Yet the facts themselves are evident. Hamilton was clearly a realist in his psychological doctrine. He does not develop his doctrine of the will, with which he coupled desire, except in fragmentary discussions of ethical import, and feeling is likewise treated only in some lectures in which he maintains that pleasure is the reflex in consciousness of the spontaneous energy of the soul, pain being the consciousness of restrained exertion. Thus he planted himself on the authority, yet the limited sphere, of human consciousness. In his logic and metaphysics the formal consequences of this standpoint are seen.

Hamilton's chief practical interest was in education, in which he distinguished himself both as a teacher and writer. His lectures in psychology, metaphysics, and logic at the University of Edinburgh were for twenty years (1836-1856) the most powerful factor in the thought of Scotland. They, together with his writings, won him widespread recognition as the most stimulating teacher, the most learned metaphysician, and the profoundest speculative thinker in Great Britain. His contributions to educational literature consist of a series of eight essays originally published in the *Edinburgh Review* during the years 1830-1836. While they have not the universal human interest possessed by those of Spencer, published some twenty-five years later, they attracted general attention, had a decisive practical effect, and contained much of permanent value. Five of them were devoted to the subject of university reform in its various aspects. With great dialectical skill and enormous learning he argued for the restoration of their ancient powers and prerogatives to the universities of Oxford and Cambridge. He contended that these universities had been absorbed by the colleges which had grown up in connection with them and usurped their time-honored functions. In the universities as originally constituted the cycle of instruction was distributed amongst a body of professors, all professedly chosen from merit, and each concentrating his ability upon a single subject. But since the Reformation the academical instruction had been monopolized by the colleges and left in the hands of tutors and fellows, appointed from favoritism, and each undertaking to teach the whole curriculum. This usurpation of the teaching function by the colleges he vigorously attacked as illegal, modern, and destructive of educational efficiency, and advocated the restoration to the universities of their former functions. The reforms which he championed have since been accomplished. The university professoriate has been resuscitated, reorganized, and re-endowed; restrictions have been removed from the fellowships and they have been thrown open to merit, the conduct of examinations and the granting of degrees has been restored to the university authorities, students are now admitted to the universities without becoming

## HAMLIN

connected with any college; and, finally, all religious tests (against which Hamilton argued trenchantly and which prevented the attendance of Dissenters and Roman Catholics) have been abolished by the universities, though not by the colleges

Hamilton was an ardent humanist. One essay was devoted to the defense of the humanities as the most useful subject of instruction. Another goes at length into the controversy between mathematics and philosophy, as to which is the more useful as a means of mental training. His conclusion is that "no study cultivates a smaller number of the faculties, in a more partial or feeble manner, than mathematics, and therefore they ought not to be made the principal, far less the exclusive, object of academic encouragement"

**HAMLIN, CYRUS** (1811-1900) — Missionary, educator, and first president of Robert College, was born at Waterford, Me., in 1811. He was graduated from Bowdoin College in 1834, and three years later from the Bangor Theological Seminary. He went to Turkey as a missionary in 1838. At the close of the Crimean War he secured from Christopher R. Robert, a New York merchant, a gift for the organization of an undenominational Christian college near Constantinople. Robert College was opened in 1860, and Mr Hamlin was its president until 1876. He was a professor in the Bangor Theological Seminary from 1877 to 1880, and president of Middlebury College from 1880 to 1885. For an account of his educational activities among the Christians, Moslems, and Jews of Turkey, see his *My Life and Times* (Boston, 1883).

**HAMPDEN-SIDNEY COLLEGE** — A small but historic institution, situated in the village of Hampden-Sidney, near Farmville, Va. Its beginning is found in measures taken in 1774, by the Presbyterian Church, to establish a "public seminary" in Prince Edward County. The prospectus of the Hampden-Sidney Academy declared that no sectarian consideration should influence the conduct of the school, a pledge kept throughout its history. The academy was opened on Jan 1, 1776. The name was a memorial to the English patriots, John Hampden and Algernon Sidney. In May, 1783, a college charter was secured from the General Assembly of Virginia, among the incorporators were Patrick Henry, James Madison, and a number of famous Virginians. The college increased rapidly in the scope of its work, number of students, and endowments up to the Civil War. From 1863 to 1866, inclusive, no students were graduated, all of them enlisting in the Confederate army as soon as they reached the age for service. At this time less than thirty boys remained in college.

The record of the alumni is remarkable. Early students included William Cabell, Governor and judge of the Virginia Court of Appeals; Joseph Carrington Cabell, co-founder with Thomas Jefferson of the University of Virginia; William Cabell Rives, twice minister to France, and representatives of many old Virginia families. From 1787 to 1789 William Henry Harrison was a student. Among the alumni there have been two members of the Cabinet, ten senators, twenty-two members of the House of Representatives, eight governors of states, and four ministers to foreign coun-

**HAMPTON NORMAL AND AGRICULTURAL INSTITUTE, HAMPTON, VA —**

This school for negroes and Indians was founded by General Samuel Chapman Armstrong (*q. v.*) in 1868 on the shore of Hampton Roads, near Fort Monroe, Va., for the purpose of providing a practical education for the children of the ex-slaves For two years it was under the control of the American Missionary Association In 1870, however, it became independent of any association or sect, receiving a charter from the state of Virginia

Hampton Institute is now an undenominational industrial school, controlled by a board of seventeen trustees The school property includes 1100 acres of land and 135 buildings, among which are a church, an academic hall, a library, dormitories, and buildings for the teaching of agriculture and the mechanical trades The number of students (1912) was 1699, of whom 81 were Indians (Indians were first admitted in 1878), 899 are negro boarding pupils, and 457 are negro children in the Whittier day school, which is used as a practice school for the training department The negro boarding pupils pay for their board and clothing, partly in cash, partly in labor, the Indians are assisted by the government in these payments But the great majority of students cannot pay their tuition, which is provided by churches, Sunday schools, benevolent societies, and individuals

Hampton Institute offers elementary and advanced academic and agricultural courses, thirteen trade courses, and courses in business, home economics, library methods, matron's work, and the training of teachers Its object is to train teachers and industrial leaders for the negro and Indian races Great stress is laid on character building and on the development of a missionary spirit in the pupils Besides the regular work on the school grounds, which includes a summer school for teachers, a farmers' conference, and a general negro conference, Hampton Institute carries on extension work of a very varied character, influencing schools and communities in all parts of Virginia and in many other Southern states More than seven thousand young people have

had the benefit of Hampton's ideals and training. They have for the most part gone back to the Western plains or to the Southern states, and there have become centers of influence — teachers, farmers, skilled mechanics, thrifty homemakers — leading their people more by deeds than by words to a higher plane of citizenship. **HANDBALL** — One of the oldest and most universally played games is that of bouncing a ball against a wall by hitting it with the open hand From this simple children's game, various difficult and complex games have been developed in different countries In Ireland the game of handball is played in a rectangular court surrounded by four smooth walls, the ball is caromed around the walls and returned with the hand In Spanish-American countries the game called pelota (ball) is very similar to handball, only the hand is reinforced by a wooden scoop strapped to the forearm Another interesting development of the "handball game" is the game of "fives," which it is claimed originated with the boys at Eton and Rugby The Eton fives court was originally formed by two buttresses of the chapel, the side obstacle, called the "pepper box," being the end of the banister belonging to the chapel steps, and the "hole" merely an accident The Rugby fives game is slightly different from the Eton game Both varieties of this game are very popular in the Public Schools of England as well as at Oxford and Cambridge

In recent years a simple game of handball has been developed in the United States This new form of the old game is rapidly growing in favor as an indoor game, and is now played in nearly every gymnasium in the coun-

try. The rules of this new game vary in different parts of the country, but the essential principles are the same everywhere. In its simplest form the game is played against a smooth surface of brick, cement, or wood, about fifteen to twenty feet wide and twelve to fifteen feet high. The floor in front of the wall is of wood or cement, the court is marked by parallel lines running back from the corners of the walls about twice the width of the walls. A transverse line across the middle of the court serves as a service line. The game is played by two, three, or four players. When there are three players, each player scores for himself when serving, and the other two players play as partners against the server. When played by four players, the game is called "doubles," and the players are divided into sets of partners who score together. The rules of the game are similar to those of lawn tennis. The server stands in the front half of the court, bounces the ball on the floor, and hits it with the open hand against the wall, the ball must land in the back half of the court and be returned by the receiver on the first bounce. The ball is then bounced against the wall and returned either "on the fly" or after one bounce on the floor, in any part of the court, until one player fails to return it or makes it bounce outside of the court. The server continues to serve until he fails to return the ball in the court when he is "out" serving. Each point missed by the receiver counts one point for the server. The game is for twenty-one points. Much interest is added to the game by the presence of a side wall or other obstruction, making possible a greater variety of difficult plays. The game is extremely popular, first, because it is easily learned and yet affords unlimited opportunity for the development of skill, second, because it may be played in any good-sized room with a smooth wall or on smooth ground adjoining a smooth building wall, and third, because all the equipment necessary for the game is a small rubber ball.

Handball is a most valuable form of physical training because it combines most of the advantages of the best athletic games. As a form of exercise it is admirable, for it brings into play all the different groups of muscles, the abdominal organs are stimulated by the bending and twisting movements, and the activity of the heart and lungs is accelerated. The game may be played lightly or vigorously, according to the strength of the players. Handball is also valuable as a means of physical education. It serves to develop agility, judgment, accuracy, and endurance. In addition to these physical and educational values, handball affords wholesome recreation of the kind that is most beneficial to students and teachers. Another valuable characteristic of handball is that it can be played outdoors as well as indoors. There are many handball courts in

the yards and on the roofs of college and school gymnasia

**HANNAK, EMANUEL** (1841–1899) — Austrian educator, born at Teschen, where he received his school education. In 1859 he entered the University of Vienna, and devoted himself mainly to the study of history. In 1866 he became a teacher in a gymnasium in Vienna, and at the same time private docent in the university. His main interest was in history and the teaching of that subject. In 1870 he gave instruction at the *Padagogium*, of which Dittes (*qv*) had charge, for the further training of teachers. He became greatly interested in pedagogy and the training of teachers. In 1874 he was appointed director of the Normal School at Wiener-Neustadt, and with this in view visited the chief normal schools of Germany. He achieved great success in this position, and through his interest in education and the after training of teachers won the support of residents and teachers. In 1881 he succeeded Dittes as director of the *Padagogium* in Vienna, his work there attracted attention not only throughout Europe, but also in the United States. In 1889 he became honorary member of the New York Industrial Association, and two years later wrote a monograph on *The Training of Teachers in Austria* for the New York College for the Training of Teachers Educational Monographs (Vol 11, No 3, pp 87–112). Besides his other activities, he took a prominent part in promoting the higher education of women, and the first German gymnasium for girls was opened at the *Padagogium* in 1891. Of his writings the majority deal with the teaching of history and textbooks in history. *Lehrbuch der Geschichte für Mittelschulen*, *Lehrer- und Lehrerinnenbildungsanstalten*, *Lehrbuch der österreichisch-ungarischen Geschichte* (1884), *Historischer Schulatlas* (1886), *Methodik des Unterrichts in der Geschichte* (1891). In 1889 he issued a new edition of K Schmidt's *Geschichte der Pädagogik*, to which he contributed the section on education in ancient times. He was a contributor to Rein's *Encyclopädisches Handbuch*, and wrote several reports on the teaching of history for international expositions.

**HANOVER** -- See GERMANY, EDUCATION IN.

**HANOVER COLLEGE, HANOVER, IND**

— A coeducational institution, the successor of Hanover Academy, a school opened in a log cabin in 1827, by the Rev John Finley Crowe, at the request of the Presbytery of Salem, Ind. The first students were sons of the Scotch-Irish Presbyterians who settled in Indiana. On Dec 30, 1828, the school was incorporated by the legislature of Indiana. The Theological Department, established to meet a condition imposed by the synod, was continued until 1840, when it was removed to New Albany, Ind., and later became the McCormick Theological Seminary (*qv*). In 1833 the institution was chartered as Hanover College, and opened on the manual labor (*qv*) system, which soon failed. On Feb 25, 1909, the charter was amended to eliminate denominational control. One trustee is nominated each year by the alumni.

The college maintains, besides the usual undergraduate courses, admission to which is based on entrance requirements of fifteen units, a summer school, a preparatory academy, and graduate courses conferring the degree of M A for one year's work in residence. There were in 1911-1912 twenty-one members of the instructing staff, and an enrollment of 260 students. C G.

**HARDENBERGH, JACOB RUTSEN** (1736-1790) — First president of Rutgers College, was educated in the academies of New Jersey, and was for several years engaged in the ministry of the Dutch Reformed Church. He was instrumental in the establishment of Queen's (now Rutgers) College, and was its first president (1770-1790). W S M

See RUTGERS COLLEGE.

**HARDIN COLLEGE, MEXICO, MO** — An institution for the education of young women, founded in 1873. High school and junior college, music, and art work are given. There is a faculty of twenty-four instructors.

**HARKNESS, ALBERT** (1822-1907) — Author of Latin textbooks and college professor, was graduated from Brown University in 1842, and subsequently studied in Germany. He was for ten years instructor in secondary schools, and in 1855 he became a professor in Brown University. He was one of the founders of the American Philological Association and of the American School of Classical Studies at Athens (*qv*). He was the author of seventeen Latin textbooks. W. S M

**HARMAR, JOHN** (1594-1670) — Classical scholar and schoolmaster, educated at Winchester and Magdalen College, Oxford. He took his B A in 1614, and was a master in Magdalen College School, Oxford, in 1617.

He became headmaster of St Albans School in 1626, whence he dates his translation of the *Janua linguarum* of William Bathe or Bateus, a Jesuit of Salamanca (1626). In 1650 he returned to Oxford as professor of Greek. He wrote school textbooks, *Praxis Grammatica*, 1622, and the *Lexicon Etymologicum Græcum*, being an edition of Scapula, with a *Lexicon Etymologicum Linguae Græcæ*, compiled by Harmar himself in 1637. He is also noteworthy as the translator of the Assembly's *Shorter Catechism* into Greek and Latin, 1659.

**HARMONY, MUSICAL** — See MUSICAL TERMS

**HARMONY, HARMONIOUS DEVELOPMENT**

— The social philosophy of the later eighteenth century was cosmopolitan, not nationalistic, in tenor. It regarded the divisions of mankind into different political states as arbitrary or artificial, and took Humanity as its ideal object of endeavor. Man was more than the citizen. Consequently the educational systems that had national, or any particularistic political or religious, ends were looked upon with hostility. In opposition to them were urged the superior claims of an education which should develop the individual as a member of humanity. The motto of such an education was the harmonious development of all the faculties of the individual, as against the partial and narrowing tendencies attributed to national and confessional systems of education. The conception of harmony of development was strengthened by the tendency toward "Hellenism" — that is, to regard the Greek personality as the normal expression of human powers. (See CULTURE.) It was also associated with the popular objective and absolute idealisms of the time, which regarded the individual as universal mind in miniature, and which treated development as the process of actualizing the latent or potential universality. Under this influence the idea of harmony took in some cases (as in that of Froebel) a romantic or even mystical turn, instead of the classic form characteristic of the Hellenic ideal. J D

See DEVELOPMENT, FROEBEL; GOETHE, HERBART, LESSING, NEO-HUMANISM, PESTALOZZI, ROMANTICISM, VOLTAIRE

**HARNISCH, WILHELM** (1787-1864) --

German educationist of the Pestalozzian school, was born in Wilsnack, near Potsdam, Prussia, attended the gymnasium at Salzwedel, and in 1806 entered the University of Halle. After about half a year his study there was rudely interrupted, as the university was closed by order of Napoleon I. He spent a year in tutoring, and then completed his studies at the University of Frankfurt-on-the-Oder. In 1809 he was called as a teacher to a private

school in Berlin, which had been founded by Plamann, a direct disciple of Pestalozzi. There he also came in contact with Jahn (*qv*), and was inspired by him with a great love of gymnastics. In 1812 Harnisch was appointed as principal of the teachers' seminary at Breslau, which institution he soon made one of the most important centers of Pestalozzian ideas in Germany. When the war of liberation began, he, with all of his students, volunteered to join the army against Napoleon, but the educational authorities refused their consent, as they regarded the work he was doing as too important to be interrupted, even on account of such patriotic motives. Nevertheless, when later on the era of political reaction set in, Harnisch, like so many other patriotic Prussians of his time, was denounced as a demagogue. He had instituted an open-air gymnasium, which had become even more popular than the famous "Turnplatz" of Jahn in the "Hasenheide" near Berlin. It was just this influence of Harnisch over the young men of the country which rendered him suspicious to the government. His "Turnplatz" was closed, and even the natural history excursions which he used to undertake with his pupils were arbitrarily interfered with. In 1822 he was even transferred to the teachers' seminary at Weissenfels, a much inferior institution, which, however, by twenty years of devoted efforts, he raised to the rank of one of the best training schools in Prussia. In 1842 he resigned his position, and lived for the rest of his life as the pastor of a village near Magdeburg.

Not only through his training of teachers, but also through his literary activity, Harnisch was very influential in shaping the character of the German public school. Like Diesterweg (*qv*), he emphasized the individuality of the pupil, but he also laid stress on the social factor in education. His contributions to the methodology of arithmetic, geometry, and geography are very important. In geography he introduced into the Prussian schools the method by which the child first studies his home surroundings (*Heimatkunde*), and from them passes on to the study of his country and of the world.

Among his works may be mentioned. *Handbuch für das deutsche Volksschulwesen*, first published in 1812, reedited by Bartels, Langensalza, 1893, two pedagogical magazines, edited by him, the one (*Der Schulerat an der Oder*) from 1814 to 1820, and the other (*Der Volksschullehrer*) from 1824 to 1828, *Die Weltkunde* (geography), Breslau, 1817, and *Das Weissenfelser Schullehrerseminar und seine Hilfsanstalten* (*The Weissenfels teachers' seminary and its auxiliary institutions*), Berlin, 1838.

**HARPEDONAPTÆ** — The philosopher Democritus (*qv*) is reported as having said, in his usual boastful fashion, that no one had as yet surpassed him as a geometrician, "not even the so-called Harpedonaptæ of Egypt." These were probably the recognized teachers of geometry among the Egyptians, since the fact that Democritus speaks of them as interested "in the construction of plane figures with proof" shows that they were more than simple surveyors. The word means "rope stretchers," and originally referred to the custom of surveyors to stretch a rope around three pegs so as to make a triangle with sides equal to three, four, and five units, respectively. This formed a right triangle, and it enabled the surveyor to run a line at right angles to a given line. The plan is still used by surveyors. It is probable, however, that the word had lost its original meaning, just as geometry (*qv*) has long since ceased to be "earth measure," and that the harpedonaptæ were the teachers of geometry of Egypt. This plan of constructing a right triangle by means of rope stretching is a very old one. It is found in China and India as well as in Egypt, and the process is pictured upon the temple at Edfu, the inscription dating from the Ptolemaic period. D E S.

**HARPER, WILLIAM RAINEY** (1856-1906). — An educator, born at New Concord, Ohio, July 26, 1856, was graduated from Muskingum College in 1870, received the degree of Ph D. from Yale in 1875, taught in minor academic positions in Tennessee and Ohio, 1875-1880; was professor of Hebrew in the Baptist Theological Seminary, Chicago, 1880-1886, served as principal of the Chautauqua Summer Schools and correspondence courses, 1884-1898, and was professor of Semitic languages in Yale University, 1886-1891. In 1891 he became head professor of Semitic languages and literature and first president of the University of Chicago. He died in January, 1906. Dr. Harper's experience and training gave him a singularly wide range of interests and sympathies. His graduate work at Yale inspired him with high ideals of productive scholarship, his duties in preparatory schools and the theological seminary revealed and developed remarkable powers as teacher and lecturer, his experiments in organizing correspondence instruction in Hebrew and his summer work at Chautauqua gave him firm faith in popular education, his contact with men and institutions evoked extraordinary capacity for leadership and organization. All these aptitudes and abilities were energized by a tireless will and directed by an original mind. The founding of a new university afforded its first president an unusual opportunity, of which he took full advantage. The characteristic features which he impressed upon the institution were (a) the division of undergraduates into two groups,

A GROUP OF AMERICAN EDUCATORS.

## HARRINGTON

the Junior College (freshmen and sophomores) and the Senior College (juniors and seniors), — a division based upon the theory that the first two years belong more properly to a six-year secondary school period, while the last two are an introduction to university studies; (b) the division of the academic year into four periods of three months each — a plan by which buildings and equipment are in continuous use, and students may be matriculated or graduated quarterly instead of annually, (c) the concentration of the student's attention for each quarter upon three, or sometimes four, courses which met four or five hours a week, (d) the inclusion as regular divisions of the institution of both university extension lecture courses and correspondence instruction, (e) the establishment of a press division as an integral part of the university, (f) the outlining of a policy of affiliation by which smaller colleges were through supervision and subsidy to be standardized, and brought into relation with the senior colleges and graduate schools. The General Education Board and the Carnegie Foundation (*qq v*) are carrying out on a national scale plans which in many respects Dr Harper hoped to realize with the University of Chicago as a center. Dr Harper's published works include textbooks for teaching Hebrew, Greek, and Latin, constructive and critical studies in the Old Testament with especial reference to the priestly element and to prophecy, and volumes of essays and addresses on Biblical, ethical, and educational subjects. ## HARRIS, WILLIAM TORREY (1835–1908)

— American educator, was born near North Killingly, Conn. After attending rural schools, he completed in New England academics his preparation for college. He entered Yale College, where he remained for more than two years, making an unusually brilliant record. Desiring greater freedom to devote himself to the study of the natural sciences, he withdrew from Yale, and removed to St. Louis, Mo., in 1857, where he remained for twenty-three years, serving first as a tutor in a private family and as a teacher of shorthand, afterwards as a principal of a grammar school, later, from 1866 to 1867, as assistant superintendent of schools, and from 1867 to 1880, as superintendent of schools. In 1880 he severed his connection with the schools of St. Louis, and, after spending some months in European travel, settled in Concord, Mass., becoming one of the founders of the Concord School of Philosophy and Literature (*q v*), and engaged in philosophic study and writing. In 1889 he was appointed United States Commissioner of Education by President Harrison, and filled that office until 1906, when he voluntarily retired. The remaining years of his life he spent in congenial study, his last service being connected with the editorship of Webster's *New International Dictionary*.

*Philosophical Contributions* — Under the influence of a young German, Brockmeyer, Harris became an earnest student of philosophy and one of the foremost exponents of Hegelianism in the English-speaking world. *Hegel's Logic* is one of the fruits of this influence. On the appearance of Spencer's *First Principles* in 1862, Harris wrote a review, but, unable to find a magazine to accept it, he founded and edited, from 1867 to 1893, the *Journal of Speculative Philosophy*, at the time the most important enterprise in philosophy ever undertaken in America. Considering philosophy as the most practical of all subjects, he soon became accustomed to interpret every question, whether of art, religion, science, politics, or education, in the light of its standards, for, as he said, "the test of any system of philosophy is the account it gives of the institutions of civilization." A thesis composed of passages from Harris's writings, and compiled in 1890 by Marietta Kies, forms the only organized presentation of his work. Although he was not a professor in a college or a university, yet he greatly stimulated the study of philosophy through the *Journal of Speculative Philosophy*, through his labors in the Concord School of Philosophy and Litera-

ture, through his educational reports and addresses, and through his personal contact, public and private, with his fellow men

*Contributions to Education* — Harris was America's first great educational philosopher. Because of his protracted, intelligent, and scientific study of the psychology, the history, and the philosophy of education he developed such insight into school problems as was enjoyed by none of his predecessors and by few, if any, of his contemporaries.

His activities and contributions in books and articles, as well as addresses, were extraordinary, whether viewed from the standpoint of quantity or quality or the range of subjects treated. The bibliography of his writings (see references) contains 479 separate titles, which cover all the important questions that have been discussed in the educational world during the last half century. Among his more important writings are to be included his thirteen annual reports of the public schools of St. Louis, which established his reputation as an educational thinker of the first rank, his report as chairman of a subcommittee of the Committee of Fifteen upon the correlation of studies, which was submitted to the National Educational Association, and which constituted an epoch-making contribution to the educational literature of our times; his report as the chairman of a subcommittee of the Committee of Twelve, which considered the problems of instruction and discipline in the rural school, his annual reports as United States Commissioner of Education from 1889 to 1906, which commanded the respect of educators at home and abroad, and by which the Bureau of Education became an educational clearing house for the world, the prefaces and introductions to the volumes of *The International Educational Series*, of which he was the editor, Webster's *New International Dictionary*, of which he was editor-in-chief, and *Psychologic Foundations of Education*, in which he sets forth in its thirty-nine chapters the psychological explanation of the more important educational factors of civilization and its schools.

In his executive work as superintendent of city schools in St. Louis and as Commissioner of Education in Washington, he demonstrated his ability to realize educational ideals born of critical observation and reflection. He was such an administrative and supervisory officer as he himself describes in an article in the *Educational Review* (City School Supervision), Vol. III, 1892, pp. 167-172.

In his contributions to education, he labored continuously to accomplish three great purposes. The first was to psychologize education. Along with other leaders in the school world, he showed the futility of the old-time psychology, with its so-called "faculties of the mind," and demonstrated the worth of the new. His second purpose was to establish faith in the school as an institution having sociological functions and value. In the *Report of the Com-*

*mittee of Fifteen* he discussed four bases for the correlation of studies: (1) the logical order of topics and studies, (2) the symmetrical whole of studies in the world of human learning; (3) psychological symmetry; (4) the pupil's natural and spiritual environment.

His final purpose was to place education upon an enduring foundation. He subjected the whole field to critical analysis, interpreting and justifying the school, and assigning to it its proper place in the scheme of institutional life. His view of the world, in which was embodied the altruistic, missionary idea at the bottom of our civilization, included the notions that education is a process of conscious evolution and that it is the only rational, reliable agency by which man may work out his destiny in harmony with the will of the Divine Being. W. S. S.

**HARROW SCHOOL** — This school, one of the seven great Public Schools of England included in the Public Schools Act, 1868, was sixth of these in the date of legal foundation, but last in its actual commencement, which took place in 1615, ranked in general estimation as third or second by virtue of its record as a resort of the rich and a producer of statesmen and men otherwise prominent in the world, especially the political world of England. Its development, however, as a great school for the aristocratic and wealthy class is comparatively recent. Unlike Winchester, Eton, and Westminster, which were especially designed as great schools to furnish men to serve in high stations in Church and State, and have done so from their beginnings, Harrow has developed in a way which its founder certainly never contemplated, and which he would possibly have resented. For there can be no doubt, alike from the station of the founder and the statutes which he prescribed, that what he meant to establish was a small local grammar school, chiefly for the poor of a small rural parish, not a great national establishment for the wealthiest of the *nouveaux riches* of the realm. The

founder was John Lyon, who lived at Preston, a hamlet in the extensive parish of Harrow in Middlesex, some twelve miles from London then, now a suburb of that ever-extending city. The whole of the property left by him produced only some £138 a year. The foundation of Harrow school, like that of Rugby (*q.v.*) a few years before, is an indication of the growth to independence and moderate wealth of a new middle class on the partial ruin of the great ecclesiastical and secular nobility which took place under Henry VIII. The era of more than princely foundations like those of Wykeham and Wolsey, great soul-purchasing colleges, had given way to the more humble charitable gifts by kindly disposed people of moderate means who had no children of their own for the benefit of the more prolific and less prosperous of their neighbors. Lyon devoted his whole possessions to the school, and that is why the process of foundation took no less than forty-four years. The first step, which on parchment was the foundation of the school, was taken on Feb. 19, 1571, the date of Letters Patent from the Queen. They recited the intention of John Lyon of Preston in Harrow "yeoman" to newly found a grammar school for the perpetual education, teaching, and instruction of the boys and youths of the parish, and to maintain two scholars at Cambridge and two at Oxford University, and the repair of the common ways between Edgware and London and surrendered lands copyhold of the manor of Harrow, which he had only bought in 1569, to the governors for the use of the school, and that not at once, but only after the death of himself and his wife Joan or Jane. It was not for another fifteen years, viz. on Jan. 19, 1590, that he drew up the ordinances and statutes for the school. These provided that within half a year after his own and his wife's death the governors were to meet and appoint a school-master, an M.A., and an usher, and if he left an heir of his body, pay them £20 and £10 each, if he left no heir (which happened), 40 marks (£26. 13. 4) and 20 marks (£13. 6. 8) a year, with 5 marks each for fire. He must have been somewhat of a reactionary in religion, as he directed that both masters should be single men, unmarried and should be removed, if they married. Another £10 was to go for thirty sermons a year in Harrow Church, which the master or the vicar might preach at 6s. 8d. a sermon. Another £20 was to be distributed, 6s. 8d. each, to the sixty poorest householders in the parish. £20 also was to go for exhibitions to four poor scholars from the school, and "of the poorest sort," two at Gonville and Caius College, Cambridge, just augmented by Dr. Caius, who lived at Ruiship in the parish of Harrow, and two at Oxford, with preference for his own next of kin born in Harrow. He then directs the governors to accumulate the rents for three years so as to provide £300 to build the school, if he did not

do it in his lifetime. But he ordered them nevertheless "to continue 20 marks a year which I the said John Lyon have used to give and pay for the teaching of 30 poor children of the parish." The governors were to set down "a meet and competent number of scholars as well of poor to be taught freely for the stipends aforesaid as of others to be received for the further profit and commodity of the said school-master." For in 1590 £26. 13. 4 a year was much below the standard of payment of headmasters of the larger schools, seeing that even in 1510 Colet had provided for his master at St. Paul's, and prices had gone up enormously since then. The Rules added to the Statutes carried out this still further. "The school-master may receive over and above the youth of the inhabitants of the parish, so many foreigners [*i.e.* non-parishioners] as the whole number may be taught and applied and the place can conveniently contain, and of the foreigners he may take such stipend and wages as he can get, so that he take pains with all indifferently as well of the parish as foreigners, as well of poor and of rich, but the discretion of the governors would be looked to that he do." As the only lodging for the masters was one room each at each end of the school, there was clearly no room for boarders, who were not contemplated. The Rules set out the curriculum of instruction in full, and the humble character of the school is conspicuously shown by the fact that only five forms are contemplated, whereas in the great schools of the time VI, VII, or VIII were provided for. Very little change had taken place since the days of the earliest Winchester and Eton curriculums in 1525 and 1530. The pseudo-Cato's *Moralia*, or two-lined adages of conduct in Latin hexameters, were prescribed in the first or lowest form, Erasmus' *Dialogues with Æsop's Fables* and Manenius' *Lines on the Four Virtues*, written about 1490, in the second form. In the third form Terence, Cicero's *Letters*, Ovid's *Tristia*. Only in the fourth form did they begin Cæsar's *Commentaries*, Cicero, *De Natura Deorum*, and Livy. In Greek Demosthenes and Isocrates, for rhetoric still was regarded as one of the principal methods and aims of education, and Heliodorus, Latin verses and themes. Hesiod is the only Greek poet, chosen because of his gnomic character. Disputations were still the means of inculcating grammar, the boys propounding to each other questions and answers. Half holidays were, as in the fourteenth century, rigidly excluded except on Thursdays. "Their play shall be to drive a top, toss a hand-ball, to run or shoot and none other." Archery shooting at the butts was still prescribed by law. Every parent on the admission of his son had to promise to allow him at all times works of devotion and piety for the great solace and encouragement of scholars occupied in learning in the same parish. To give effect to this intention the Queen willed

and granted that there should be and therefore erected a grammar school consisting of a master and usher in the parish to be called the Free Grammar School of John Lyon. She incorporated a body of six governors, headed by Gilbert Gerard, Esquire, the attorney-general, to take care of the possessions, revenues, and goods of the school, and gave them license in mortmain to take and hold lands to a value not exceeding £100 a year. As if to show the absurdity of the modern theory that a Free School (*q v*) did not mean one free from ecclesiastical jurisdiction, the charter provided that if the governors failed to elect a new master on a vacancy, the Archbishop of Canterbury should appoint, and if governors made statutes, they should do it under the advice and consent of the Archbishop. The Bishop of London also had some visitatorial powers.

The phrase in the charter, *de novo erigere*, "to erect anew," has been thought to show the existence of a school at Harrow before Lyon's foundation. But probably the words simply mean to erect a new school. But there is, as usual in Tudor foundations, some evidence of a school in Harrow before. In 1567, Richard, son of William Gerard, one of the governors named in the charter of 1572, admitted a scholar of Caius College, Cambridge, was described as having been at Harrow School for four years, *ie* from 1563. But this may only have been the unendowed school of thirty boys maintained by Lyon. But a letter of the Roper family speaks of the destitute children of a keeper of Enfield Chase and Hyde Park being sent to Harrow School by Queen Mary, 1554-1558; but this again may be Lyon's unendowed school. A lease of some of the school property in 1596 speaks of "the newe school or church house of the parish," which shows that the school was then kept in it, and it may have been so kept previously to Lyon's day. That there was no school there in the fourteenth century seems to be shown by two extracts from the rules of the Rutny manor. In 1384 the court directed the seizure of the goods of "John Intowne, a bond-tenant (*ie* a serf), for that he against the will of the lord, the rector, delivered his son Wilham into remote parts to learn the liberal arts." In 1356 the bailiff of the manor answered for a horse taken as a distress from the same John Intowne, because he placed William his son, a bond-tenant of the lord, to school without the license of the lord. That was the way in which the Rector of Harrow in those days manifested the love of the Church for learning and advanced education, under the very nose of the Archbishop of Canterbury, to whom Harrow belonged and where he not infrequently resided.

Though the charter of 1572 thus purposed to found and erect the school and its governing body, neither had a more than nominal existence. It was not till 1575 that Lyon made his first endowment of land at Harrow after

the deaths of himself and his wife. He also made further additions, and in 1590 he issued the Statutes for the government of the school. Five articles defining the relation between the masters and the parents and children followed the statutes.

Still the school was not established. Lyon died Oct 11, 1592, and his brass, with his portrait and that of his wife, may be seen in Harrow Church. She died only in August, 1608. Soon after the governors began building, but in 1610 a chancery suit in the interest of the road repair stopped proceedings. The school, which had more than double the stipulated sum, was only opened in 1615, a year after Charterhouse. The number of free boys was fixed at forty, ten more than Lyon had maintained in his lifetime. What number of foreigners then came, if any, we do not know. There is no evidence that the school was anything more than a small parish school such as Lyon intended until after the Restoration. Indeed, in 1668 the master went off, apparently to Lincoln Grammar School, without notice as to promotion. In 1669 William Horne, an Eton scholar and fellow of King's College, Cambridge, and undermaster under his father at Eton, was appointed master of Harrow. From that time dates the development of Harrow as a great public school on the same lines as Eton, and to its succession of Etonian masters Harrow owes its real creation, as Eton did to its succession of Winchester masters. Horne was allowed, contrary to the statutes, to marry, and was assisted to rent a house in the village in which to take boarders. A letter among the Verney papers shows that by 1650 there were "six score" or 120 boys there and several boarding houses, besides the headmaster's, kept by "Dames" as at Eton. The charge was £22 a year in the headmaster's, and £14 a year in the other houses, the parish supplying sheets, towels, pewter plates, a porringer and spoon. The archery prize of a silver arrow, shot for among the boys, dressed in gorgeous costume, which became as a social function a great attraction to the school, was instituted at this time. Horne died in 1685. After a short five years of William Bolton, who had been usher at Charterhouse, came another Etonian and King's man, Thomas Brian, who held office till his death in 1730. With the powerful assistance of James Brydges, the magnificent Duke of Chandos, who had built his palace of Canons at Stanmere in the parish, Harrow became, like Westminster, though in a much less degree, an aristocratic school for the Whigs, Eton and Winchester having fallen under Tory influence. The first eminent Harrovian, a ward of the Duke's, George Brydges Rodney, who won the great naval victory over the French in the West Indies, was a pupil of Brian's, who in 1721 numbered 144 boys. His son-in-law and successor, Cox, however, drank, and let the school down to fifty. He was removed in 1746, and again a Whig Etonian,

Thomas Thackeray, the grandfather of the novelist, restored prosperity. Samuel Parr and Sir William Jones, of oriental fame, were among his pupils, Parr being head of the school at fourteen. He was afterwards second master there. But it was under Robert Sumner, another Etonian, that Harrow owned its first great statesman in Richard Brinsley Sheridan, the indicter of Warren Hastings. The number went up to 232. From this time the free boys began to fall. In 1780 there were only eight. Under Benjamin Heath was the first Harrow prime minister, the ill-fated Spencer Perceval. From 1785 to 1805 the school under the mastership of Joseph Drury again achieved considerable success, under Drury were five future prime ministers of England, Lord Byron, and many other members of aristocratic families. The appointment of Dr. Charles Butler (1805-1829) led to a second revolt, in which Byron took part, but the boys were soon won over by the new headmaster. As the school increased in numbers and popularity in the country generally, the local connections grew weaker, the governors were no longer resident, as was required by Lyon's Statutes, the poor were not being educated according to the bequest, and such poor boys of the locality who did attend fared ill at the hands of the aristocratic "foreigners." An appeal was made in 1809 to Chancery to enforce the statutes, but without avail. Harrow did not escape the general demoralization which seems to have prevailed in the large English schools at the beginning of the nineteenth century, there was a lack of discipline, a general viciousness and brutality, to control which required a very strong headmaster and a complete change of attitude. But some reforms were made, although classics continued to be the main part of the curriculum. Butler, himself a senior wrangler, introduced a little natural and experimental philosophy and Euclid, while under Drury English essays and verse had already been encouraged, in 1829 the first school magazine, *Harrovian*, appeared, and between 1829 and 1836 French was compulsory. The fifteen years following Butler's administration, despite the ability and scholarship of the headmasters, were years of rapid decline, partly as a result of the financial panic which then took place, partly through a distrust of the Public Schools. In 1844 Charles J. Vaughan (*qv*), a young man of twenty-eight, a Rugbeian and the favorite pupil of Thomas Arnold (*qv*), became headmaster, and at once there began a brilliant period in the history of the school. The numbers rose from 69 in 1844 to 315 in 1847, the moral tone of the school was raised, the monitorial system was improved, and a staff of earnest, capable teachers was brought together. The residents of Harrow again raised their objections that the school was not fulfilling the intentions of the founder. Vaughan skillfully placated them by establishing an English

form in 1853, in which modern subjects suitable to the needs of the sons of farmers and tradespeople were taught. To "secure the boys from interference or annoyance from the Public School," the boys were "to regard themselves as entirely separate in all respects from those at the Public School as at present existing." Out of this arrangement there developed the Lower School of John Lyon. On the retirement of Vaughan in 1859, Dr. H. Montague Butler became headmaster, and established the school on its present basis. The Tercentenary Festival was held in 1871, with the passing of the Public Schools Act in 1868 new statutes were drawn up for the government of the school, benefactions continued to pour in, new buildings sprang up, and land was bought around the school to secure the seclusion and retreat which the suburban growth of London was making less possible. The curriculum was no longer monopolized by the classical studies, music and school songs became an important feature of the school under Mr. John Farmer, whose influence spread to many other schools, and in 1882 the broader relations of the school with the world were emphasized by the founding of a mission among the poor in Notting Hill, London. Under Bishop Welldon, Dr. Wood, and the present headmaster, Rev. Lionel Ford, Harrow continues to maintain the best tradition of the great Public Schools and to exercise an influence through its distinguished alumni in church and state, in the army, in professional and commercial life.

As at present organized, the school is divided into classical and modern sides, the latter intended for preparation for the army, civil service, or business. No boys are admitted under twelve years of age. The number of boys is about 600, the majority being on the classical side. There are seventeen boarding houses. Athletics play an important part at Harrow, as at most English schools, cricket is perhaps the most popular game, interest centering as it does on the annual match with Eton. Other sports are local football games, swimming, squash and rackets, a rifle corps was established in the days of Dr. Vaughan.

## HARTFORD THEOLOGICAL SEMINARY, HARTFORD, CONN

— Founded in 1834 by the Pastoral Union of Connecticut as the Theological Institute of Connecticut at East Windsor Hill, moved to Hartford in 1865, and present title adopted in 1885. Students, men and women, who already hold college degrees are admitted. A knowledge of Greek is necessary for pursuit of the regular course, which extends over three years. Specialization is encouraged in one of five groups: Old Testament, New Testament, History, Systematics, and Practices. Courses in psychology and pedagogy are given in the Hartford School of Religious Pedagogy, and courses in comparative religions in the Hartford School of Missions, both of which institutions are affiliated with the seminary. The seminary confers the degrees of Ph D, S T M, B Sac Mus, and B D, on completion of the necessary courses and requirements, and the degree of S T D, *honoris causa*. There are twenty-seven members on the teaching staff.

**HARTLEY, DAVID** (1705-1757) — Physician and philosopher, educated at Cambridge. His chief work, *Observations on Man*, was published in two volumes in 1749. Hartley was the first to apply systematically the doctrine of the association of ideas, which he got from Locke and Gay. Sense impressions leave copies of themselves in the form of simple ideas of sensation,—the elements of which the mental life is compounded. By association these get the power to call up other ideas, and by connection with ideas of pleasure and pain, which constitute desire and aversion, they become also the starting point of actions. Action is due in the beginning to a mechanical overflow from sensory into motor channels. Hartley's medical interest led him also to formulate a physiological doctrine to which he attached great importance. This is the theory, suggested by Newton's *Principia*, of a physical

## HARTLEY UNIVERSITY COLLEGES

cause of all mental facts in vibrations of the infinitesimal medullary particles. He does not press, however, the question of the precise relation between mind and body, but is content to postulate a correlation. His theory of association is practically independent of the vibration theory, which last was usually neglected by his followers. Hartley's treatment of education is incidental. The only application of the association doctrine which comes in very close contact with its methods in detail is his discussion of the development of language through hearing, speaking, reading, and writing. In a general way, however, Hartley has a high sense of the value of education, which is the great remedy for the needs of the time, and whose method is to be determined by tracing back the process through which associations have arisen. Since affections and passions are only aggregates of simple ideas, and the objects which excite them are due to association, moral education is amenable to the association doctrine. All motives go back in the end to personal pleasures and pains, but since desire can be shifted by a perfect fusion from the sensation to its antecedent, Hartley proclaims vigorously the possibility of "disinterested" motives, which morality and religion demand. These represent the end of all training, and Hartley advocates greater attention in education to sacred learning, and less to the "lewd poets". His doctrine of determinism also exalts the importance of education by basing development on the influence of environment, and the absence of any definite instinctive bias in his psychology goes to make training practically all-powerful. "With proper incentives and restraints few children would miscarry." "It is evident that children may be formed and moulded as we please." "If two beings whose affections and passions are at present in different proportions be exposed for an indefinite time to the same impressions and associations, they will at last become perfectly similar and even equals." The application of this as a means of social reform and reconstruction is, however, of later date. Hartley himself conceives that the traditional results of association are largely to be followed. The value of physical education also has some recognition, especially in one of his medical tracts. This also has a moral value in aiding to restrain desires. A K R.

**HARTLEY UNIVERSITY COLLEGES, SOUTHAMPTON, ENGLAND.** — An institution founded in 1852 under the will of Mr Henry R. Hartley to afford facilities for a

liberal and professional education to the inhabitants of Southampton and the neighboring countries. Attention was at first paid only to preparation for army and civil service examinations, in 1871 a science and art department was opened and preparation was given for the examinations of the Science and Art Department, South Kensington. In 1896 work of a university character was begun, and in 1902 the institution was recognized as a university college and received grants from the Treasury. At the present day classes are conducted in arts and sciences, medicine and dentistry, engineering, education in the day training department recognized by the Board of Education. Evening classes are held in technical, commercial, industrial, and scientific subjects, and facilities are afforded for students who were unable to attend a secondary school to attend a course of evening work to qualify for entrance into the day classes. Hartley College does not grant degrees but students may be prepared for degrees, in other universities. Public lectures are conducted by the institution. Support is given by the Treasury and several local county and municipal authorities in and around Southampton. A proposal is now on foot to secure a university charter for the college. In 1910 the teaching staff consisted of twenty-eight teachers and the student enrollment was 230 in day and 500 in evening classes.

England, Board of Education. *Reports from Universities and University Colleges in Great Britain*. (London, 1908.)

**HARTLIB, SAMUEL** (?1600–1670) — The best known educationist of his time in England. He was the son of a Polish merchant by his third wife, who is supposed to have been an English lady. He came over to England from Germany (probably from Elbing) in 1628, and engaged in educational and other social plans. Hartlib, in a remarkable appeal to the House of Commons (about 1660), says that he had tried “to serve his generation,” and amongst other things “by erecting a little Academy for the education of the Gentry of the Nation, to advance Piety, Learning, Morality and other exercises of industry not usual then in common schools.” Evelyn (*qv*) states that he had relieved Hartlib’s necessities, and evidently the latter was too lavish for his means in helping on educational and social plans. Yet in 1646 a pension of £100 a year was conferred upon him by Parliament, and afterwards this was raised to £300 a year.

In 1647 Hartlib wrote his *Considerations tending to the Happy Accomplishment of England’s Reformation in Church and State*, in which he urges that it is the duty of the magistrates “to see schools opened, provided with teachers, endowed with maintenance, regulated with constitutions, and to have instructors and

overseers to the observance of good order in this business.” Without such reforms of schools “no other work of Reformation,” says Hartlib, “will ever be effectual.” His grading of schools was similar to that of Comenius (*qv*) and to that of Dury (*qv*). A further scheme in which the three joined, and about which Dury also wrote, was the establishment of an “Office of Address,” to be established in London and to deal with both bodily and spiritual matters. It was to be useful to the poor, by helping them to employment and by distinguishing the industrious from the idle. This is, apparently, the first suggestion of a government bureau of labor. Next, the office was to be the medium of communication in “matters of the mind.” The warden of the office was to keep all kinds of registers, inventories, catalogues, and lists containing the peculiar objects whereof he should furnish information for address to such as shall desire it, or to whom it might be advantageous for public good to send information. In religion the office was to help to rectify mistakes and prevent the increase of divisions and disorders about disputed opinions or religious practice. This was the especial mission of Dury, with whom Hartlib worked in close conference. In education, the Director of the Office of Address was to advance learning, in accordance with Lord Bacon’s plea, and to “help to perfect Mr. Comenius’s undertakings, chiefly on the Method of Teaching Languages, Sciences and of [founding] ordinary schools for all ages and qualities of scholars.” Lastly the Office of Address was to encourage the dissemination of information about inventions, so as to increase their public serviceableness. Communications were thus to be established throughout the workers and thinkers of this country and also with the *savants* abroad. The important functions which he thought the State could perform in intellectual progress may be further seen in his *Description of the Famous Kingdom of Macaria, showing its excellent Government, wherein the Inhabitants live in great Prosperity Health and Happiness; the king obeyed, the Nobles honoured and all good men respected, Vice punished and Virtue rewarded. An example to other Nations. In a Dialogue between a Scholar and a Traveller*, 1641 [15 pp]. To Hartlib’s annoyance, *Macaria* was satirized in John Sadler’s *Olbia* in 1660, where reference to “education of the children, in Sciences, Arts and Manufactures” is brought in, after the manner of Hartlib.

Besides writing on education, Hartlib was a center of a most remarkable educational group. John Milton (*qv*) wrote the *Tractate* in response to Hartlib’s suggestion. So Dury was stimulated by him. Other friends were John Hall (*qv*), John Webster (*qv*), George Snell (*qv*), and Hezekiah Woodward (*qv*). As belonging to Hartlib’s group, united in the desire to promote the advancement of learning

under Baconian influence, were also John Pell, in his *Idea of the Mathematics*, Sir William Petty (*q.v.*), Abraham Cowley (*q.v.*), and John Evelyn (*q.v.*) Hartlib was also in close touch with progressive leaders abroad. He was apparently one of the leaders in the proposed invitation to John Amos Comenius (*q.v.*) to come over to England and to have Chelsea College assigned for his educational purposes

In 1650 Hartlib wrote a notable tractate, *London's Charity enlarged, Stilling the Orphan's Cry*, in which he suggested to Parliament that it should grant £1000 toward work for the employment of the poor and for the education of poor children. He describes the laws and officers necessary for the control of children in a work-house

On the theoretical side of education, Hartlib published the following interesting collection of tractates: *A True and Readie Way to Learn the Latine Tongue, Attested by three excellently Learned and Approved Authors of Thre Nations, Eilhardus Lubinus, a German, Mr. Richard Carew of Anthony, in Cornwall, the French Lord of Montaigne, Presented to the Impartial both Public and Private Considerations of those that seek the Advancement of Learning in those Natons*. By Samuel Hartlib, Esq., 1654. Other educational works in the publication of which Hartlib took part are (1) *Comatuum Comenianorum præludia ex Bibliotheca S. H. Oronæ*, 1637 (The Address to the Reader, 2 pp., in Latin, is by Hartlib.) (2) *Reverendi et clarissimi viri Johannis Amos Comenii, Pansophiæ Prodromus*, etc. London, 1639 (8 pp. in Latin. To Reader by Hartlib.) (3) *A reformation of Schooles, designed in two excellent Treatises. The first whereof summarily sheweth the great necessity of a general Reformation of common learning. What grounds of hope there are for such a Reformation. How it may be brought to pass. The second answers certain objections ordinarily made against such undertakings, and describes the severall Parts and Titles of Works which are shortly to follow. Written many years agoe in Latine by that Reverend, Godly, learned and famous Divine Mr. John Amos Comenius. Now translated into English and published by Samuel Hartlib, for the generall good of this Nation*. 1642. (4) *A Continuation of Mr John Amos Comenius School Endeavours. Or a Summary Delineation of Dr Cyprian Kinner Silesian his Thoughts concerning Education. Or the Way and Method of Teaching. Translated out of the Original Latine transmitted to Sam Hartlib, and by him published, etc.* 1648. (See KINNER, CYPRIAN.) (5) *An Essay for Advancement of Husbandry-Learning; or propositions for the erecting a Colledge of Husbandry: and in order thereunto for the taking in of Pupills or Apprentices, etc.* 1651. (This invites contributions to be sent into Samuel Hartlib for the object named.)

Hartlib's name is also associated with the publication of many other collections, together

with original contributions on such subjects as husbandry, "Luciferous and fructiferous" experiments, planting of fruit-trees, setting out of land, silk-worms, bees; chemical, medicinal and chururgical addresses, an invention of engines of motion, "a common writing."

F. W.

#### HARTSHORN MEMORIAL COLLEGE, RICHMOND, VA. —

An institution for the education of colored young women, established in 1884. Normal preparatory and normal, college preparatory and college, industrial, and music departments are maintained. The college course leads to the degree of A. B. The majority of the students are in the normal departments.

**HARVARD, JOHN (1607-1638)** — The first donor to Harvard College. The facts as to Harvard's life have become fairly well known in recent years. He was the son of a butcher, Robert Harvard, and was born in November, 1607, in High Street, Southwark, close to London Bridge. He was christened on Nov. 29, 1607. His father died of the plague in 1625. His mother, Katherine Rogers, married twice again, first to John Elletson or Ellison (who died in June, 1626), and then to Richard Yearwood (or Yarwood), Member of Parliament for Southwark. She outlived them all, and inherited money from each. She died in 1637, having made her will in 1635 in favor of her sons John and Thomas. John, who survived his brother, entered at Emmanuel College, Cambridge, on Dec. 19, 1627, and graduated in 1631, proceeding as Master of Arts in 1635. He married in 1637 Ann Sadler, the daughter of a Sussex clergyman, and, his mother being dead, sailed for New England, where Cambridge and Emmanuel men had preceded him. He became a townsman of Charlestown, Mass., on Aug. 6, 1637. "His house was on the site now marking the southerly corner of Main Street and the Alley leading up to the Town Hall" (J. Winsor, *Memorial History of Boston*, I, 395; III, XXII). On Nov. 2 he took "the Freeman's oath" and he and his wife became church members four days

later. Though he, apparently, was not ordained, he acted as assistant to the Rev Z. Symmes, and preached. On Apr. 26, 1638, he became a member of a law-drafting committee. This possibly was a committee appointed to deal with the question of Gorges and the Charter, which had reached an acute stage in April, 1638. Harvard was, for that age, a wealthy man as well as a scholar, and seems to have won at once respect and position in the new settlement. But his brief course was nearly run, and he died of consumption on Sept. 14, 1638, childless. By a nuncupative will he left half of his estate (subsequently valued £779, 17s. 2d) and his excellent library of 320 volumes to the proposed school or college at Newton (*i.e.* Cambridge). The matter was not left in abeyance, and the college was built forthwith. In December, 1638-1639, it was ordered by the General Assembly that "the Colledge agreed upon formerly to be built at Cambridge shall be called Harvard College." J. E. G. de M.

**HARVARD UNIVERSITY, CAMBRIDGE, MASS.** — The oldest educational institution in the United States. Established by vote of the General Court of the Colony of Massachusetts Bay, Oct. 28, 1636, and made possible through a legacy in 1638 from John Harvard, the college was given the name of Harvard in 1639, and held its first commencement in 1642. The name Cambridge was adopted for the town which was to be the seat of the college because many of the leading men of the colony were graduates of the University of Cambridge, John Harvard himself having been a Master of Arts of Emmanuel College, Cambridge.

*New England's First Fruits*, a tract published in 1643, contained the following paragraph. "After God had carried us safe to *New-England*, and wee had builded our houses, provided necessaries for our livehood, reared convenient places for Gods worship, and settled the Civill Government: One of the next things we longed for, and looked after was to advance *Learning*, and perpetuate it to Posterity, dreading to leave an illiterate Ministry to the Churches, when our present Ministers shall lie in the Dust. And as wee were thinking and consulting how to effect this great Work, it pleased God to stir up the heart of one Mr. *Harvard* (a godly Gentleman and a lover of Learning, there living amongst us) to give the one halfe of his Estate (it being in all about 1700 l.) towards the erecting of a Colledge, and all his Library after him another gave 300 l. others after them cast in more, and the publique hand of the State added the rest: the Colledge

was by common consent, appointed to be at *Cambridge*, (a place very pleasant and accomodate) and is called (according to the name of the first founder) Harvard Colledge."

The bequest of Mr. Harvard was the first of the private gifts for education which have distinguished American history from that day to this, while the act of the colony in 1636 marks the beginning of state aid to higher institutions of learning in America.

In 1642 an act was passed "establishing the Overseers of Harvard College", and in 1650 "the charter of the President and Fellows of Harvard College" made the college a corporation, to consist of a president, five fellows, and a treasurer, in whom should vest the property of the institution, and by whom, under the general control of the Overseers, its affairs were to be directed. These acts have been supplemented by a long series of legislative enactments, and in 1780 were explicitly confirmed, with important reaffirmation of ancient rights and privileges, in a section of the Constitution of Massachusetts entitled "The University." Upon this foundation still rests the legal existence and organization of Harvard University.

Most of the presidents of Harvard in the seventeenth and eighteenth centuries were drawn from the prominent ministers of the neighboring churches, but two (John Rogers, 1682-1684, and John Leverett, 1708-1724) were laymen. The most distinguished of the early presidents were Increase Mather (1685-1701) and Edward Holyoke (1737-1769).

In the struggle in the colony between the Congregational clergy and the more liberal elements the college early tended toward the liberal side, and a crisis occurred about 1700. Cotton Mather (1663-1728), a leader on the conservative side, failed to be elected to the presidency, which his father had held, and it became in many ways evident that the orthodox Calvinistic party could no longer rely upon Harvard College. Mather accordingly interested himself in the college already established in Connecticut, and in 1718 was influential in securing for that new enterprise a generous gift from Elihu Yale, a merchant of London. Later in the eighteenth century another noteworthy epoch in the history of the college was made by the events of 1735-1745. At that time the president, the professor of divinity, and the other instructors took ground against the religious revival known as the "Great Awakening," and vigorously opposed the tenets and utterances of George Whitefield, the eloquent English evangelist, whose work had deeply stirred New England. The theological development in the direction of liberal views was completed in 1805, when, after a bitter controversy, Rev. Henry Ware, an avowed Unitarian, was elected to the Hollis professorship of divinity. The result of his election was the definite withdrawal of the Calvinistic party from the support of the college.

and the foundation of Andover Theological Seminary in 1808 and Amherst College in 1821. For more than half a century from the date of Ware's election, Harvard was a distinctively Unitarian college, controlled by the Massachusetts aristocracy whose capital was Boston.

In the seventeenth and eighteenth centuries Harvard received some financial aid from the State, but its support was mainly due to a continuous stream of private gifts from donors both in England and in the American colonies. The largest gift of the seventeenth century was a bequest of £1000 from Sir Matthew Holworthy. Among many large benefactions of the eighteenth century the most important were those of Thomas Hollis, a Baptist and the leading layman of the English nonconformists. Besides sending numerous gifts of money and books, he founded in 1721 the Hollis professorship of divinity, which is thus the oldest professorship in North America.

At the Revolution the college cordially sympathized with the American cause, and the names of nearly all the most prominent Massachusetts patriots are to be found on its list of graduates. In 1776, after the evacuation of Boston by the British, the honorary degree of LL.D. was conferred on George Washington, whose headquarters were then in Cambridge.

The endowment of the college at the opening of the Revolutionary War amounted to less than £17,000, together with certain rents of real estate. The corporation proceeded to invest substantially the whole of this property in Continental and Massachusetts certificates of public debt, so that the very life of the college hung on the success of the American arms. The result of their courageous and patriotic policy was that in 1793, after the close of the war, the endowment of the college was estimated at upwards of \$182,000, invested in good securities. The nineteenth century saw a steady enlargement of this endowment from alumni and friends of the college, gradually swelling into the great annual gifts of the present day.

In the nineteenth century, down to the Civil War, the influence of Harvard College was extended beyond Massachusetts, sometimes as many as a fifth part of its students being drawn in those years from the South and the Middle States. It was intimately involved in the active intellectual life of New England, and a large proportion of the great literary figures of the time were graduates of Harvard (Longfellow, a graduate of Bowdoin, was professor here, 1836-1854, and spent his life in Cambridge), most of the New England poets and historians, and nearly all the liberal theologians and transcendental philosophers, were Harvard men. The most noteworthy of the presidents were John Thornton Kirkland (1810-1828), Josiah Quincy (1829-1845), and James Walker (1853-1860). In this period the resources of

the university were increased, professional schools of medicine, law, divinity, and science built up, and the distinction of the college maintained by the names of such professors as Jared Sparks, Edward Everett (both of them afterward for short terms presidents of the college), Joseph Story, George Ticknor, H. W. Longfellow, J. R. Lowell, Benjamin Peirce, Louis Agassiz, Asa Gray, and O. W. Holmes, and of many eminent men among the alumni.

In these years a number of dormitories and other buildings were added to the equipment of the university and the endowment increased from \$242,000 in 1800 to \$2,250,000 in 1869. The list of the college faculty grew from fifteen members in 1810 to twenty-four in 1869. In 1803-04 the freshman class in the college numbered 57, and the total number of students in the university was 233 (besides a fair number of medical students), in 1868-69, the corresponding figures were 128 and (including the professional schools) 1043.

In respect to educational organization, the curriculum during the Puritan and provincial periods down to 1800 was gradually freed from the distinctively theological cast which it bore to some extent nearly to the end of the eighteenth century, and in 1790 had come to consist of Latin, Greek, mathematics (including astronomy), English composition, philosophy (metaphysical, moral, and political), theology, natural philosophy, and (the only option) either Hebrew or French. With the one exception noted, it remained a prescribed course of study for all alike, and was well fitted to introduce students to the branches of knowledge at that day essential to a liberally educated man (See COLLEGE, AMERICAN, the section on the administration of the curriculum).

In the earlier part of the nineteenth century the general intellectual activity of the time, united with the influence of several professors who had studied at German universities, caused many changes in the discipline and course of study of Harvard College. The efforts of George Ticknor (professor 1817-1835) and others led to tentative progress in the direction of an elective system of studies; and chemistry, geology, history, political economy, and other modern studies were brought in.

At the same time pregnant changes took place in the government of the university. Until 1800 the fellows of the corporation had been largely ministers, after that date it became customary to elect but one clerical fellow. (Since 1884 no clergyman has been a member of the corporation.) The distinction of the position was thereby decidedly enhanced. At one time Joseph Story and Lemuel Shaw, two of the greatest jurists that this country has produced, and Nathaniel Bowditch, the foremost American mathematician of his day, made three out of the five fellows. In 1843 the Board of Overseers was opened to ministers not of the Congregational denomination, and

HARVARD UNIVERSITY.

Copyright by W. T. Littig & Co

a still more important step was taken when the Commonwealth relinquished its representation in the overseers. From the beginning the Governor and other high public officers, including the council and later the whole state senate, had had seats on this board, but in 1865 the right of election was wholly transferred to the alumni of the college, and since that time the state has had no share in the administration of Harvard. This was the culminating event of a long struggle in which the orthodox party of Massachusetts, allied with certain political interests, had sought to wrest from the Boston Unitarians an effective share in the control of Harvard. But the result was not a partisan victory, it came about through the relaxation of the rancor of ancient controversies under the engrossing tasks and opportunities of a new period of national life, and it brought to the university no restriction of scope. By permitting the introduction into the overseers of persons not resident in Massachusetts, and in other ways, under what proved to be more democratic influences, the new organization led to an increase in size and power far beyond expectation.

Since the Civil War Harvard has shared in the growth upon which the whole North and West of the United States then entered. Its history in this period is the history of the administration of Charles William Eliot (born 1834, president 1869-1909). President Eliot was able by his foresight, breadth of interest, and skill in organization and administration, by his single-minded devotion to high aims, and by the dignity of his personal character, to use the new forces of the time, command innumerable gifts aggregating a great sum of money, and hold the enthusiastic loyalty of a rapidly increasing and able staff. In the forty years of his presidency he was able to see Harvard widely extend the borders of its work, quadruple in number of students, and establish its position as a great national university, influential throughout America and honored beyond the seas. His efforts were especially devoted to the complete application of the elective principle in undergraduate studies, the maintenance of strict standards of examinations for entrance and graduation, the inclusion of all branches of knowledge and the arts in the opportunities offered to students, the requirement of a college degree for admission to the professional schools, and the insistence on the highest scientific ideals in all the graduate and professional departments. His administration deliberately followed the principle of freedom as a moral force in the methods of student discipline and in the regulation of the undergraduate curriculum, and was conspicuous for firmness, generosity, and justice in the treatment of the faculties and officers of instruction.

The present president is Abbott Lawrence Lowell, at the time of his election professor of

government in the university. The chief progressive policies of his administration thus far have been the introduction of a system by which undergraduates are compelled to adopt a definite aim in their choice of elective studies, the strengthening of the purpose to keep professional and technical work out of the undergraduate course of study, and a more careful fostering of the solidarity of undergraduate life.

In the government of Harvard the Corporation, a self-perpetuating body composed of the president, five fellows, and the treasurer, is charged with the executive control of both the financial and the educational administration. The Board of Overseers, consisting of thirty members elected by the alumni together with the president and treasurer of the university, possesses undefined but extensive powers. The consent of the overseers is requisite for the election of the members of the corporation and of professors, and for the appointment of all major officers of instruction and government. To the overseers are referred all important constitutional acts of the corporation and the several faculties, and they have the duty of inspecting every part of the university through numerous special committees, and of making recommendations to the proper administrative authorities.

The president is a member of all the faculties as well as of the governing boards, and in practice always attends their meetings. Professors and other higher officers are appointed by the corporation and overseers on the nomination of the president, after informal consultation with the professors of the department. In the medical faculty alone the board of full professors formally nominates to professorships. For the professional schools the several deans have, as a rule, complete responsibility for organization and educational work, with the control of the budget; but Harvard College and the Graduate School of Arts and Sciences are under the immediate direction of the president, the deans being mainly concerned with the supervision and discipline of the students.

The faculties are four: Arts and Sciences, Divinity, Law, and Medicine, each consisting of all those officers giving instruction in that faculty who are appointed for a term of more than one year. Instructors who are members of a faculty, as well as all professors, have a vote, and, save in the Faculty of Medicine, the higher grades of instructors possess no privileges not enjoyed by the younger men in the faculty. It is characteristic of Harvard that the heads of departments in the Faculty of Arts and Sciences have no authority of control, but are merely chairmen, who are frequently changed. This permits the younger men to fill these positions, and is believed to be of advantage to the university by enabling the assistant professors and instructors to exert a stronger influence for progress in educational methods. The faculties hold frequent meetings, — the Faculty of Arts

## HARVARD UNIVERSITY

and Sciences often meeting once a week, — and are active legislative bodies. The discipline of students and other administrative duties are devolved in the larger faculties upon administrative boards; and the Faculty of Arts and Sciences is divided into departmental committees, to which are intrusted important powers of detailed administration.

Harvard College is the heart of the university. With it is intimately associated the Graduate School of Arts and Sciences. By an anomaly among the professional schools, the Graduate School of Applied Science and (until 1912) the Graduate School of Business Administration are also under the Faculty of Arts and Sciences. There is no division into an undergraduate and graduate faculty of arts and sciences; and the courses of study in Harvard College and the Graduate School of Arts and Sciences are not sharply distinguished.

Entrance to Harvard College is by examination only, and many candidates are annually rejected. By the new system of requirements, adopted in 1911, the adequacy of each candidate's program of preparatory studies is separately investigated, and, if the program is found satisfactory, the result of his education is tested by four examinations: (1) in English, (2) in Latin or (for a candidate for S B) a modern language, (3) in mathematics or physics or chemistry, and (4) in that one which a candidate may choose out of a list of seven specified subjects. This plan, which is intended to bring Harvard into ready contact with the better high schools of all parts of the country, is at present maintained parallel to the old system, under which every subject studied in the preparatory course is tested by examination. Of the total number entering in the ten years 1901–1910, 44 per cent came from public schools, 56 per cent from private and endowed schools. Of the eighty-three candidates admitted under the new plan in 1911, 84 per cent came from public schools, 16 per cent

## HARVARD UNIVERSITY

from private and endowed schools. The degrees of A B and S B are given in Harvard College, the chief difference being that candidates for A B are required to pass an entrance examination in Latin.

Harvard has not favored the plan of interweaving the college and professional courses into a "combined course" for the two degrees, but has insisted that a student shall have substantially completed his work for a college degree before entering the professional school. A considerable number of students, however, complete all the requirements for the bachelor's degree in three or three and one half years.

The degrees of A B and S B and all other ordinary degrees are given only for resident work, except in so far as work in another institution is counted for advanced standing. In order to provide for students in the Summer School and in the extension courses, the degree of Associate in Arts was established in 1910. It calls for the same number of courses to be regularly attended as for a bachelor's degree, but requires neither entrance examinations nor technical "residence."

Since 1886 attendance at religious services has not been required of students. In the university chapel morning prayers are held daily, with a regular service on Sunday morning. The religious services are directed by a board of five preachers of various denominations, under the chairmanship of a resident professor who is in the relation of a college pastor. Each preacher gives several weeks of continuous service at the college, conducting the services and consulting with students. The work of the chapel is supplemented by the usual voluntary associations of students, — undenominational, Episcopal, and Roman Catholic.

The various departments of the university, with the date of establishment and the number of students and of members of the faculty in 1911–1912, are shown in the following table.

	DATE	STUDENTS	NUMBER IN FACULTY NOT INCLUDING THE PRESIDENT
I Faculty of Arts and Sciences			179
Harvard College	1636	2262	
Graduate School of Arts and Sciences	1872	454

<sup>1</sup> In addition to students (521) taking courses given by Harvard instructors in the Boston "Extension Courses."

## HARVARD UNIVERSITY

The total number of members of faculties, omitting names counted twice, was 248 in 1911-1912. In addition, over 450 officers holding annual appointments were members of the teaching staff.

For admission to candidacy for a professional degree a prior degree from a recognized college or technical institution is regularly required, except in the Dental School, for which, however, entrance requirements with examinations are strictly enforced.

Among the more notable recent developments in professional instruction is the transformation of the School of Applied Science (formerly called the Lawrence Scientific School) from an undergraduate technical school, parallel to the college, into a graduate school, resting on a previous college course and including the following departments, in each of which an appropriate professional degree is conferred: engineering (civil, mechanical, and electrical), mining, metallurgy, architecture, landscape architecture, forestry, applied physics, applied chemistry, applied zoology, and applied geology.

Recently established (1908) is also the Graduate School of Business Administration, designed through courses in accounting, commercial law, economic resources, industrial organization, banking and finance, transportation, and insurance to fit college graduates for administrative positions in the business world.

The Divinity School, originally Unitarian, is now an undenominational school of theology, and its faculty includes professors of three different denominations. With it has now become associated Andover Theological Seminary (Congregational), in consequence of the removal of the latter to Cambridge in 1908 and its formal affiliation with the university. The courses of the Faculty of Divinity and of the Andover faculty are so planned as to form one systematic body of instruction.

The clinical facilities of the Medical School have hitherto been provided at the Massachusetts General Hospital, the Boston City Hospital, and ten other hospitals and dispensaries in and near Boston. These facilities are now to receive an important increase by the erection, already begun, of the Peter Bent Brigham Hospital on land adjoining the property of the Medical School. This great hospital, which has a large endowment, is to be conducted, and its chief officers have been selected, by a joint arrangement between its trustees and the Medical School.

The chief scientific establishments of the university, besides the various laboratories, are the following: Mineralogical Museum (1793), Botanic Garden (1807), Astronomical Observatory (1843), Museum of Comparative Zoology (1859), Gray Herbarium (1864), Peabody Museum of American Archaeology and Ethnology (1866), Bussey Institution (agriculture) (1871), Arnold Arboretum (1872), Harvard Forest at Petersham, Mass. (1907).

## HARVARD UNIVERSITY

The University Library includes the main collection in Gore Hall and the libraries of the various departments, of which the library of the Law School (in 1911, 126,000 volumes, 14,250 pamphlets) and of the Museum of Comparative Zoology are the most important. The Divinity Library has now been united with the library of Andover Seminary to form the Andover-Harvard Theological Library of upwards of 100,000 volumes, without doubt the best equipment for the work of theological scholars to be found in this country. The University Library contained, July 1, 1911, 1,587,734 volumes and pamphlets, and its age, careful selection, and many valuable accessions by special gift give it a distinction far beyond its size.

Affiliated with the university are Radcliffe College (for women, established under an earlier name in 1879), Andover Theological Seminary (1808), already mentioned, and the School for Social Workers (1904). Extension teaching to persons mainly engaged in other occupations is carried on not only in the Summer School, but also through a share in the winter courses given in Boston under a committee representing Harvard, Tufts, the Massachusetts Institute of Technology, Boston College, Boston University, the Boston Museum of Fine Arts, Wellesley, and Simmons.

The grounds used for academic purposes (not including investments in real estate) cover about five hundred acres in Cambridge and Boston, together with the Engineering Camp property of seven hundred acres at Squam Lake, New Hampshire, the Harvard Forest of two thousand acres at Petersham, Mass., and the Observatory at Arequipa, Peru. The value of the buildings is estimated at upwards of \$12,000,000. The total income-bearing endowment of the university, July 1, 1911, was about \$24,300,000. The annual net income from all sources in 1910-1911 was upwards of \$2,400,000, made up approximately as follows: income from investments, \$1,140,000; fees and rents from students, \$955,000; miscellaneous income, \$58,500; gifts for immediate use (excluding gifts for buildings), \$268,000. The expenditure was approximately as follows for administration, \$103,000; educational purposes, \$1,368,000; scientific research and other activities, \$526,000; aids to students, \$184,000; repairs and care of the buildings and grounds, \$166,000. The gifts and bequests to the university, large and small, from countless benefactors, have averaged for the ten years 1901-1911 over \$1,740,000 annually.

Harvard University draws its students from every part of the United States, but a little less than one half of the whole number usually come from the neighboring population of the Massachusetts cities and towns. In the College 56 per cent of the students were from Massachusetts, 4 per cent from the other

New England states, and 40 per cent from outside of New England. A large proportion of the students both in Harvard College and in the graduate schools support themselves in part by their own work during their course. The scholarships and other beneficiary aid granted annually to students in Harvard College amount to upwards of \$65,000. In the professional and other graduate schools upwards of \$90,000 is annually available for this purpose. All aid is given specifically from endowments or from university income, never in the form of remission of the charge for tuition.

In Harvard College student life on all its sides and undergraduate athletic organization are highly developed. The most important athletic contests are those with Yale; next to these in student interest come games and races with Dartmouth and Cornell. The more conspicuous student clubs are local organizations, not connected with the fraternities of other colleges; and but few of the society buildings provide chambers for students' lodgings. The social organization of the undergraduates in the college is wholly distinct from the life of the graduate and professional students.

The following inscription, set high over the stage in Sanders Theater, well states the ideals which have guided the history of Harvard.—

**HASSLER, FERDINAND RUDOLPH** (1770-1843) — Textbook author and first superintendent of the United States coast survey, was educated in Switzerland. He was for some years instructor of mathematics in the United States Military Academy, and afterwards professor in Union College. He organized the United States Coast Survey, and was its first superintendent. His works include textbooks on arithmetic, astronomy, geometry, and trigonometry, besides numerous publications on scientific subjects.

W S M

**HASTINGS COLLEGE, HASTINGS, NEB.** — A coeducational institution opened in 1882 under the control of the Synod of Nebraska of the Presbyterian Church. Academic, collegiate, normal, music, and oratory departments are maintained. The entrance requirements are equivalent to about fifteen points of high school work. The three courses of the college, classical, scientific, and philosophical, lead respectively to the degrees of A B, B S, and Ph B. The faculty numbers fourteen members.

**HATCH ACT.** — See AGRICULTURAL EDUCATION

**HAUN, JOHN ERNEST CHRISTIAN** (1748-1801) — Educator who carried through a reform of the school system of Gotha (*qv*) at the end of the eighteenth century, when the schools had fallen into decay. He was appointed to the teachers' training school at Gotha by Ernest the Wise (*qv*) in 1780, and three years later became inspector of country schools. In spite of much opposition on the part of the clergy and nobles who protected the incompetent teachers of the time and feared a possible increase in taxation, Haun succeeded in securing a better class of teachers, a milder form of discipline, and sounder educational methods. Haun was the author of *The common-school method or practical instruction for inspectors and teachers of every*

**HAVEN, JOSEPH** (1816-1874). — Educational writer, graduated at Amherst College in 1835. Subsequently he studied at the Union and Auburn Theological Seminaries. He was professor in Amherst College (1850-1858), Chicago Theological Seminary (1858-1870), and the University of Chicago (1871-1874). He was the author of *Mental Philosophy* (1857), *Moral Philosophy* (1859), and *History of Philosophy* (1876) W S M

**HAVERFORD COLLEGE, HAVERFORD, PA** — The successor of Haverford School, established in the spring of 1830. The school was founded in order to provide a "guarded education" for the sons of members of the Society of Friends. A by-law in the charter provides that the twenty-seven trustees of the self-perpetuating Board of Managers shall be members of the Society of Friends. This board consists of a president, a treasurer, and a secretary, and twenty-four trustees elected annually in three classes of eight members, each class to serve three years. In 1856 the school was changed to a college, and was authorized by the legislature to grant degrees; but previously to this time the course had been as extended as in most colleges. It was still hampered with a preparatory department, which was not abolished until 1861.

The college maintains the usual undergraduate courses, admission to which is by examination only. Degrees conferred are A B, B S, and M A for one year's graduate study in residence. Fraternities are prohibited. Although the income of Haverford College is exceeded by that of about 115 colleges and universities in the United States, only eight of these pay higher salaries to professors; and the least rich of these eight has an income six times larger than Haverford. Only five American colleges have a smaller proportion of teachers to students (1 to 6.5). To the smallness of this ratio and to the unusual excellence of the instructing staff a large measure of Haverford's efficiency is due. The enrollment in 1910-1911 was 150 students. The faculty consists of twenty-four members. C. G

## HAWAII

Reference:—

Haverford College Alumni Association, *History of Haverford College for First Sixty Years of its Existence*. (Philadelphia, 1892)

**HAWAII, TERRITORY OF** — A group of eight islands in the Pacific Ocean, located 2100 miles southwest of San Francisco. There are some fifteen islands, large and small, but only eight are inhabited. These eight islands have a combined area of 6449 square miles, or about the size of Connecticut and Rhode Island combined, and about twice the size of Porto Rico. The total population in 1910 was 191,909, or about thirty to the square mile. This was composed of Japanese, 79,520, Chinese, 21,666, Portuguese, 22,701, Hawaiian, 26,108, Part Hawaiian, 11,912, Americans and Europeans, 14,409; Porto Ricans, 4896. The native race is slowly dying out, having decreased from about 250,000 in 1800 to 142,000 in 1822, 49,044 in 1872, and to 26,108 in 1910. Schools are maintained on only five of the islands, the other three being small and having very few inhabitants. The territory is organized into four counties, viz. Hawaii (the largest island), Maui, Oahu (including the city of Honolulu), and Kauai (including the island of Molokai).

**Historical** — The Islands were known by the Spaniards for about a century previous to their formal discovery and the introduction of civilization by Captain Cook in 1778. Near the close of the eighteenth century they were united, by conquest, under one king, Kamehameha, and continued as a united kingdom until the revolution and abolition of the monarchy on Jan. 16, 1893. A provisional government and a constitutional convention prepared the way for the proclamation of a republic on July 4, 1894. The new republic applied for admission to the American Union, and a treaty of union was prepared, but later withdrawn by President Cleveland. When the Spanish War broke out, the republic of Hawaii was annexed by a joint resolution of the United States Congress, passed July 7, 1898, and on June 14, 1900 the congressional act organizing the territory of Hawaii went into effect. Since that time Hawaii has been governed by its own territorial legislature, and by a governor appointed by the President of the United States, and as a territory.

The educational history of the archipelago extends over a period of about ninety years. Soon after their arrival in 1821 the members of the first company of missionaries interested themselves in educational matters, the first spelling book having been printed in 1822. This may be regarded as the first step toward popular education in these Islands, but in the beginning it was an education of adults rather than of children. Between the years 1823 and 1827 a peculiar system of schools sprang up and spread rapidly over the Islands, and

flourished for about ten years. The chiefs and their immediate attendants were the first pupils. From 1830 to 1840 the American missionaries maintained model schools at each of their stations. From this time the attendance of adults fell off rapidly, and the principal attention was thereafter given to the education of children. In 1831 the missionaries established Lahamalahana Seminary, on the island of Maui, chiefly as a training school for native teachers and preachers. Industrial training was from the first a prominent feature of the curriculum. A printing press and book bindery were attached to the school, numerous textbooks were published, and in 1834 the first newspaper was issued. The school has since been incorporated as a part of the public school system.

The history of the public schools of Hawaii extends over a period of about seventy years, the first school law having been enacted in 1841 by the king and chiefs in council. In 1843 a Department of Public Instruction was organized, and the official at the head was given the rank of Minister of the Crown. This position was filled by Hon. W. Richards, and, at his death in 1847, he was succeeded by Rev. R. Armstrong, the father of General S. C. Armstrong, of Hampton fame. In 1855 the department was remodeled and placed under a Board of Education, whose president exercised the same powers and was charged with the same duties as those formerly belonging to the Minister of Public Instruction. In 1896 the administration of the public schools was again raised to the rank of an executive department, to be presided over by a minister and a Board of Commissioners, it being provided that the Minister of Foreign Affairs should be *ex officio* Minister of Public Instruction. The act of Congress organizing the territorial form of government provided for a Superintendent of Public Instruction instead of an *ex officio* minister, but otherwise made little change. Some additional school laws have been enacted by the territorial legislature, but the form of organization remains very much as it was outlined in the revised school law of 1896. In 1909 a School Fund Commission was created, to investigate and report on methods of raising school funds. The report was made, and the recommendations enacted into law in 1911. A salary schedule, a school budget, and a committee on school estimates were provided for, and the school appropriations made a first charge on the treasury.

**Present School System** — At the head of the school system of the islands is a board of six school commissioners and a Territorial Superintendent of Public Instruction, all of whom are appointed by the governor of the Islands. No person in holy orders or a minister of religion is eligible for appointment, and not more than two women shall serve on the board at any one time. The commissioners

serve without pay, while the salary of the Superintendent of Public Instruction is fixed at \$6000 per year. The Superintendent and three commissioners, or four commissioners in his absence, form a quorum for the transaction of business. This body, which has the functions of a State Board of Education, has general charge of the school affairs of the Islands, appoints and removes subordinate officers, fixes all salaries, and adopts rules and regulations, not inconsistent with law, for the government of teachers and pupils, and its officers and agents, and for the proper carrying out of the general scheme of education for the territory. It is responsible for the conduct of all educational affairs, which are under its entire charge and control. It may establish schools for secular instruction, at such places and for such terms as in its discretion may seem advisable and which the funds at its disposal will permit. It regulates the course of study to be followed, and may classify the schools as it deems proper. The schools established may include normal schools, high schools, kindergartens, schools for technical instruction, boarding schools, and evening schools, as well as day schools. Classes for such instruction may be established in any school. All school property is in its name and possession. Teachers' conventions or institutes may be called or permitted, and the schools may be closed to enable teachers to attend them.

The Superintendent of Public Instruction, when present, acts as president of the board, signs all warrants and official acts or documents, and presents a biennial report covering the work of the schools to the governor of the territory. A Secretary, together with such assistants and office help as may be necessary, is appointed by the commissioners to look after the business affairs of the department. He acts both as a secretary and a business manager, keeps a record of all proceedings, conducts all correspondence, keeps a record of all financial transactions, and is responsible for all records and documents of the department. He acts under the direction of the board, and holds office at its pleasure.

For the purposes of supervision and inspection the Islands are divided into three inspection or supervisory districts, and a traveling deputy superintendent, known officially as a Traveling Normal Inspector, is appointed for each. Visits are made by these officials to each school about three times each year. They also hold meetings of the teachers for the purpose of giving advice and promoting the interests of education; make inspections of grounds, buildings, and equipment; and serve as a means of communication between the Superintendent of Public Instruction and the teachers and the people. The islands of Oahu and Kauai comprise the first inspection district; the Islands of Maui and Molokai

## HAWAII

the second district, and the large island of Hawaii the third district. Each of these islands is in turn divided into one or more school districts, for each of which an agent is appointed by the Board of Commissioners, to serve under the Traveling Inspectors and to act as a kind of supervising principal for a group of schools. For each school having more than one teacher one of the number is designated as principal. The distribution of schools at the close of the year 1910 was as follows —

ISLAND	PUBLIC SCHOOLS			PRIVATE SCHOOLS		
	Districts	Schools	Teachers	Districts	Schools	Teachers
Hawaii	9	58	153	4	9	32
Mau	4	33	79	3	12	41
Molokai	1	9	9	1	1	3
Oahu	5	36	193	2	30	189
Kauai	5	17	55	2	3	4

All private schools are subject to the supervision of the public educational authorities. Private schools can only be established by permission, based on a written petition setting forth the names of the pupils and parents, the name or names of the teacher or teachers, and the approval of the parents. If the teachers possess the necessary qualifications and are approved by the public school authorities, a permit is issued authorizing such a private school.

**Educational Conditions** — The system of public instruction in the Hawaiian Islands resembles somewhat the county school systems of some of the Southern states, in that the schools of the Islands are managed as a unit, and by one board of education. The result is that there is a uniform system of education throughout the Islands. The course of instruction, the standards for teachers, and the salary schedule are uniform for the same kind of work throughout the Islands. The schools are maintained by appropriations and the proceeds of general taxation, and all salaries and other expenses are paid by warrants on the treasury. No differences exist among teachers on the basis of race, sex, color, nationality, politics, or religion. The sole basis and medium of instruction in all public and private schools is the English language. Tuition is free in all public schools. Free textbooks are furnished to those too poor to provide them. Attendance from six to fifteen years is compulsory. Private schools may be selected by parents, if they prefer, but all children of school age must attend some school taught in the English language. A system of truant officers, or school police, enforce the compulsory education law in the country districts as well as in Honolulu. All teachers and children must be medically examined and be free from disease.

## HAWAII

Both the total population and the school population are very mixed. For 1910 the statistics as to teachers and children in the public and private schools were as follows —

NATIONALITIES	PER CENT OF PUPILS		NO. OF TEACHERS	
	Public	Private	Public	Private
Hawaiian	16.01	3.25	72	11
Part Hawaiian	10.28	4.56	142	22
American	1.83	2.18	180	168
British	41	34	35	16
German	61	45	7	2
Portuguese	14.70	4.51	33	11
Scandinavian	20	07	7	2
Japanese	22.04	2.47	—	5
Chinese	8.43	2.82	8	12
Koreans	58	09	—	3
Porto Ricans	1.30	49	—	—
Other Foreigners	1.99	39	5	14
Totals	78.38	21.62	489	269

It will be seen from the above that five nationalities — Hawaiian, part Hawaiian, Portuguese, Japanese, and Chinese — represent over 90 per cent of the total school enrollment in the Islands.

The course of study as outlined for the schools of the territory covers the usual eight grades, and is much like that to be found in American schools. Nature study, illustrative work, manual work, calisthenics, and music run through from the first grade, sewing and carpentry are taught under the head of manual work, and agriculture has recently been introduced as a phase of nature study. Domestic science is taught in a number of schools. Public high schools are maintained at Hilo, on the island of Hawaii, and at Honolulu, on the island of Oahu.

**Teachers and Training** — The territory employed 489 teachers in 1910, and 269 were employed in private schools, in addition. The statistical table given above shows the cosmopolitan nature of the teaching force, as well as of the pupils in the schools. About 21 per cent of the public school teachers and about 30 per cent of the private school teachers are men.

Examinations for teachers' certificates are held at least once each year, usually during the summer vacation. Grammar grade and primary grade certificates are granted to those who pass. The examinations for the primary certificate are only open to those who have had one year of professional training, one year of teaching experience, or who are graduates of a high school, and the examinations for the grammar grade certificate are only open to those who hold primary certificates. Holders of a university degree, a normal school diploma, a life certificate, or of life grammar grade certificates issued in the states, may be granted a grammar grade certificate without examination. Life diplomas for the territory are also granted.

For the purpose of developing a teaching force from among those born and reared on the Islands, a territorial normal school has gradually been developed. It is located at Honolulu. It began, about twenty years ago, as an afternoon class to help those teachers who cared to attend. In 1895 it received government recognition, and a training school was developed. In 1905 a normal school building was completed and occupied, and the school now offers courses of instruction for those coming direct from the grammar schools, who constitute about 80 per cent of the enrollment, and also a two-years' course for graduates of the high schools. The school is accredited by the California State Board of Education as of equivalent rank to the California normal schools. A large proportion of the teachers are still drawn from the mainland, though the native trained teachers are said to possess superior adaptability.

**Other Institutions** — Besides the high school and the Territorial Normal School at Honolulu, island of Oahu, and the high school at Hilo, island of Hawaii, the territory maintains or assists in maintaining the Boys' Industrial School and the Girls' Industrial School, both located on the island of Oahu, and the Lahamaluna School, located on the island of Maui. The two industrial schools are reformatory in their work. The curriculum of the boys' school is largely agricultural and manual, while that of the girls' school is largely along the line of domestic work. The Lahamaluna School, whose history dates back to 1831, is a school for natives who wish to combine industrial training with general instruction. There are five classes in the school, covering about the five grades from fifth to ninth inclusive. Bookkeeping, military drill, printing, blacksmithing, carpentry, and agriculture are prominent in the work of the school. The total enrollment in 1910 was one hundred and five, made up of sixty-four Hawaiians, thirty part Hawaiians, six Japanese, four Chinese, and one Portuguese.

The United States Department of Agriculture has maintained an experimental station in Honolulu since soon after annexation, and in 1907 the Hawaiian College of Agriculture and Mechanical Arts was established. This institution is substantially the same in character as institutions of a like kind on the mainland. It is supported in large part by territorial appropriations, but also receives from the United States the same annual appropriation (\$50,000) as is given the agricultural colleges of the different states, and an additional appropriation of \$30,000 for the agricultural experiment station.

**Private Schools** — The Islands have a number of private schools, some of which are of considerable importance. The Kamehameha Schools at Honolulu are worthy of especial note. This institution was established under

the provisions of the will of a Mrs. Bishop, a Hawaiian lady of high rank, who left the bulk of her large property in the hands of trustees to endow a school for the education of children, wholly or in part of native blood. There is a large boarding school for girls, and a boys' school combining manual and technical instruction with the ordinary school branches. The school also maintains a preparatory department. The institution is well provided with workshops and appliances, and ranks as a secondary manual training school. Oahu College is another institution worthy of especial mention. Founded by American missionaries in 1841, chartered as a public institution in 1849, and rechartered as a college, as well as a preparatory school, in 1853, the institution has grown with time and has accumulated a considerable endowment. A large number of the other private schools are under Catholic Church control. E P C.

See NEW YORK, STATE OF

**HAWTREY, EDWARD CRAVEN** (1789–1862) — One of the greatest headmasters and later provost of Eton College (*qv*). It was under his influence that reforms and innovations were introduced which gave Eton a prominent position in scholarship. Hawtreys was born at Burnham, near Eton, of a family that for generations had been connected with the college. After being himself educated there and at King's College, Cambridge, where he became fellow, he acted as private tutor for three years. In 1814 he was appointed assistant master at Eton by Dr. Keate (*qv*). He at once began to exercise an excellent influence on the pupils who came into contact with him by his high standard of scholarship and culture (in addition to the classics and Hebrew, he was a master in German, French, and Italian) and encouraged a wide range of reading. In 1834 he became headmaster and in-

augurated a series of much needed reforms in organization, equipment, and curriculum. He divided up the large classes which had prevailed, secured a special room for the sixth form, of which he took personal charge, introduced examinations and a competitive basis in class-work, provided better dormitories and improved the living conditions generally, closed the old Christopher Inn which had long been the center of excesses, and secured the abolition of Montem (1847). Much of his influence with boys was due to the introduction of a new spirit of sympathy; instead of the harsh discipline meted out by Dr Keate, the boys were treated as gentlemen. In the first six years he had to meet with much opposition from the then provost, Dr Goodall, but in his successor, Dr Hodgson, he found a sympathiser and collaborator in many of his reforms. Under Hawtreys mathematics and modern languages were encouraged, better textbooks and methods of instruction were introduced, athletics and theatricals were promoted, and everything was done to provide interests to replace idleness and waste of time which merely led to bullying, brutality, and license. In 1852 Hawtreys became provost and supported the improvements of his successor in the headmastership. Hawtreys was a man of remarkable culture and literary and artistic taste, a lover of books, he collected a large library and encouraged the collection of a school library. His influence on Eton was as great as that of Arnold on Rugby, and, if it did not spread so generally on English education, this was due as much to the unique position of Eton as to the fact that Arnold was himself a teacher of so many teachers and that the Rugby spirit was published to the world in *Tom Brown's School Days*.

**HAYNE, THOMAS** (1582–1645) — Second undermaster at Merchant Taylors' School, 1605, and then usher of Christ's Hospital, 1608. He was a Leicestershire man, B.A., Lincoln College, Oxford, 1605. He gave £400 to buy lands or houses in or near Leicester to provide a rent of £24 forever for the maintenance of a schoolmaster at his native place, Thrusington in Leicestershire, to teach ten poor children, and for the maintenance of two poor scholars in Lincoln College to come from the Free School at Leicester or from the school at Milton, the schoolmaster to have £12 yearly and the two scholars £6 yearly. Hayne was regarded as a scholar, "beloved of learned men and particularly respected by Selden." His two educational books are: (1) *Linguarum cognatio, seu*

*de Linguis in genere et de variarum Linguarum Harmonia Dissertatio*, 1639 (2) *Grammatices Latinae Compendium* (1640) written in Latin, while the most necessary rules are expressed in English opposite to the Latin, that the one may facilitate and give light to the other. Hayne deserves recognition for his simplification of Lily's Grammar, but his book is now perhaps most valuable for its history of Latin Grammar in England up to his time, contained in the "Address to the Judicious Reader." This is to be found reprinted in Foster Watson's *English Grammar Schools*, pp 253–254 F. W.

**HAZELWOOD SYSTEM** — See HILL, THOMAS WRIGHT.

**HEADACHE** — A common complaint among school children. Usually it is not an ailment, but a symptom, — of eyestrain, decaying teeth, nervous fatigue, or the like, or it may be of impending acute disease. Some have maintained that there is a special form of headache due to the conditions of school life, *cephalalgie scolaire*. Under certain conditions this may fairly be maintained, for in certain schools where hygiene is ignored the congestion from prolonged sitting, the stooping posture, the strain upon the eyes and brain combined with the dry, overheated, stagnant, and impure air, are likely to produce headache, and while the headache is merely a symptom of perhaps general physical *malaise* it may fairly be attributed directly to the school. The studies by Key of Sweden and Holst and Magelssen in Christiania in Norway indicate that in only a very small percentage of cases is the headache of pupils caused by the school work. Apart from acute or chronic disease perhaps the most common causes of headache are the dry over-

## HEADMASTER

heated air of the schoolroom, decayed teeth, astigmatism, and indigestion among the children.

When children complain of headache they should be treated sympathetically by the teacher and usually the physician or nurse should be called or the child should be sent home. Continued recurrence of headache in a pupil should lead the teacher to make a careful search for the cause, and the discovery of the real cause is often of the first importance for the educator. The correction of a sense defect or a slight change of regimen will often accomplish wonders for the comfort and success of the pupil.

**HEADMASTER** — A term used in England to denote the principal of a secondary school. Only in a few private secondary schools is the term used in America. The use of the word did not become general until the nineteenth century. Until then the distinction among members of a teaching staff was not that of headmaster and assistant master but between master and usher. Other terms were pedagogue, *ludmagister*, master, High Master (still in use at St. Paul's School, London, and the Manchester Grammar School), Chief School Master (Wellingborough), or *Archidascalus* (Westminster Statutes), while the usher was also known as undermaster, submaster, surmaster, *hypodascalus* (Westminster), or *ostiarus* (Manchester Grammar School). The term "head" alone was frequently used of the chief officers of colleges and universities as early as the fifteenth century, and sometimes also of the principals of schools.

The term is also applied popularly to principals of elementary schools, but the official designation in government regulations is "Head Teacher."

**HEAT-SPOTS** — Points on the skin which are especially susceptible to stimulation from warm objects.

See COLD-SPOTS; PRESSURE-SPOTS; PAIN-SPOTS.

## HEATING OF SCHOOL BUILDINGS

### HEATING OF SCHOOL BUILDINGS —

It is not the function of a schoolman to decide between those features of heating systems wherein technical engineering knowledge is involved. School boards should employ competent engineers to install the heating system in large buildings designed for school purposes. But it should be remembered that there are many conditions entering into successful heating appliances for schools not so vitally necessary in those designed for homes or commercial buildings. It is the duty of superintendents, principals, and teachers to advise in such matters and to understand in a practical way the most economical and effective use of any system installed. In general a schoolman has opportunity to know far better the practical results of any heating system designed for schools than the engineer. Hence, there are certain demands from the school point of view which all successful heating systems must fulfill. Besides, outside of the larger city schools most heating systems are installed without the guidance of competent engineers, and very frequently the principal or superintendent is the only advisor in such matters.

**Standards in Heating Schools** — The peculiar demands in large schools on heating systems may be stated as follows: (1) The heat should be generated in some central heating plant, either in the building or outside of it. (2) It must be delivered in the schoolroom in such manner as to be equally distributed. (3) It should be automatically regulated so as to prevent in the temperature of the room a variation of more than one or two degrees. By the use of thermostats this is now possible, and no heating system for schools is complete without an adequate supply of thermostats. No special discussion of these is needed here, for they are safely and effectively installed only by engineers of experience and skill. It may be well to say, however, that all janitors as well as principals of schools should thoroughly understand the principle upon which they operate in order to know when they are properly adjusted. (4) Heating systems should be planned to meet, without undue strain or effort, the lowest temperatures of the locality. This is a very important precaution, and it is false economy on the part of boards of education to neglect it. (5) Due account should be taken of the disturbing effect of strong winds during the winter season. This modifying influence of winds on the effectiveness of heating systems has not received the amount of consideration it deserves at the hands of either the engineer or the school superintendent. In the bleaker or more wind-swept areas of the country strong winds are frequently fatal to the effectiveness of what would otherwise be an adequate heating system. (6) Heating apparatus should be constructed and located with scrupulous regard for the safety and sanitary demands of the school. All stoves, furnaces, chimneys, firerooms, coal

bins, or oil tanks should be so located and so constructed as to make it practically impossible for fires to start from these, or for dust, smoke, or odors to escape into the building. If steam is used as the thermal medium, the boiler capacity should be ample, so that a perfectly safe low pressure system can be used and yet furnish promptly and regularly an adequate amount of heat. If necessity demands a high pressure system, a registered engineer must be employed, and every precaution in the way of safety devices should be used. (7) There should be connected with each heating plant, especially in cold climates, some efficient system of introducing moisture into the air. While, strictly speaking, this is not a part of a heating system, it is so intimately connected with the effectiveness of the system, as well as the sanitary side of school life, that it deserves a great deal more thought than it has hitherto received in this country. (8) The location of a heating system with reference to the even distribution of the heat in the rooms is often a consideration of prime importance. With steam or hot water as the medium, the difficulty here suggested is more easily overcome, but with hot air furnaces the success or failure of the whole plant may depend on relative location. (9) Heating systems ought not to be divorced from ventilating systems, and hence the installation of the former should always have due regard to the quality of the air in the schoolroom as well as its temperature. Direct radiation systems therefore should never be used in schoolrooms save in the way of an auxiliary. In the northern latitudes it is sometimes necessary, to avoid expense, to use auxiliary direct radiation to secure adequate heat. (10) It is a matter of great economy in the milder climates of the country to be able to secure from a heating system a quick response with the use of a minimum amount of fuel. For it frequently happens that a little heat is needed for an hour or two in the morning, and none for the rest of the school day. Here the greater economy of a hot air furnace over hot water or steam in such climates is very clear. (11) Other things equal, it is always better to draw the air to be forced through the heating coils, from the south side of buildings, because experimental tests show in general a decided difference in temperature between the air on the north and south sides of the building. Suppose the air on the north is at the freezing point, on the south side the thermometer would show 37° F. This would mean the saving of practically one seventh of the fuel, for this five-degree difference in temperature means practically one seventh of the amount of heat necessary to bring a freezing temperature to that required in the schoolroom.

**Systems of Heating.** — *Stoves* — Having stated these general, but fundamental, considerations, some detailed suggestions deserve attention. The old-time box stove has not gone from the country schools, and is yet frequently

found in village schools, notwithstanding the fact that the jacketed stove has been much advertised and has proved both economical and far more sanitary. There are many varieties of jacketed stoves on the market, but the essential features are the same in all. There are four main reasons why the ordinary stoves in all country schools should give place to jacketed stoves or hot air furnaces. (1) A jacketed stove materially aids in ventilation (*q.v.*) (2) By its use more equable heat can be maintained. (3) Better distribution of heat to all parts of the room can be secured. (4) Such stoves can be more advantageously located in schoolrooms than ordinary stoves.

It is of course clear that the aid to ventilation mentioned above is only operative during cold weather. Many of these stoves have evaporating devices which are especially helpful in severe weather, in preventing the air from becoming too dry to breathe healthfully, and also, through this added moisture, in reducing the degree of temperature required for comfort. A temperature of 65° F. with proper humidity is as satisfying in cold weather as 70° F. when the air is abnormally dry.

**Hot Air Furnace** — The hot air furnace or heater is simply a modification of the jacketed stove, or perhaps, speaking chronologically, a jacketed stove is a modification of the hot air furnace. The essentials of this furnace are: (1) A large fire box, and combustion chamber so carefully made as to permit no possible escape of gas, smoke, or soot save through the smoke chimney. (2) The fire pot and combustion chamber are surrounded with a jacket of brick, cement, or some good nonconducting material with sufficient space between it and the heated furnace for an easy circulation of air. (3) The fresh air duct opens directly underneath the fire pot and into the air space around it, so that as the air about the radiating surface is heated and moves upward, cool air from without will take its place. (4) This warmed air passes by means of the force of a fan or simply by the force of gravity, first to a centrally located chamber from which the ducts leading to the various rooms radiate. One branch of these ducts is also connected with a cold air chamber. By means of dampers, managed by a thermostat placed in a classroom, the temperature of the room can be kept approximately at the degree required. There are some serious defects connected with hot air furnace heating that should be considered carefully. (1) Unless they are constructed and set with the greatest care, there is always some danger from gas escaping from the fire box or combustion chamber into the air to be delivered into the schoolroom. The danger is especially glaring if the furnace is too small to furnish sufficient heat without very heavy firing. For it is evident that such fires would tend to warp, crack, or displace the radiating parts of the fire box or combustion chamber, thereby offering an opportunity for the es-

cape of gas or smoke. Besides, if overheated, such furnaces permit the passage of carbon monoxide directly through the metal plates. (2) There is danger from overheating the air in furnaces, and rendering it dry, harsh, and "lifeless." Again, the only safeguard for this defect is to have a furnace of such dimensions that it will never be necessary to overheat the air in order to introduce sufficient heat into the schoolroom. Much warm air, instead of little hot air, is the correction to apply here. The amount of humidity needed can be supplied in a number of ways, but this topic cannot be discussed adequately here. (3) It is a difficult matter to properly apportion the ducts leading to the various rooms, so that, under the force of gravity or the uniform pressure of a fan, each room will get the amount of heat and fresh air needed. There have been more serious blunders made in this regard than perhaps in any other connected with the installation of heating plants. Long pipes, with short turns, no sheathing to prevent radiation and far too constricted to deliver a sufficient quantity of air without much friction, have been conspicuous causes for the failure of many expensive furnace installations. No part of a heating or ventilating system needs the advice of an expert engineer more than the construction, location, and the proportioning of the ducts designed to carry the heated air to the schoolroom. This is especially true in connection with furnace heating. (4) It is more fluctuating than hot water, or steam heating.

There are some advantages in furnace heating that are worthy of note. (1) It is more economical in mild weather when artificial heat is needed for only a fraction of the school day. (2) It requires less time to get results, for it heats quickly and is more direct than hot water or steam. (3) It is cheaper to install than hot water or steam and, if properly proportioned to its load, it is far less expensive to keep in repair. (4) It does not require attention in cold weather during holidays as hot water or steam does. (5) It is of simple construction and does not require expert knowledge to handle, as does steam or hot water heaters.

*Steam Heating* — Steam heating can be used for direct radiation, indirect radiation, or a combination of both. The advantages of this system for schools may be stated briefly as follows. (1) It furnishes a steady, continuous heat of comparatively low temperature, and hence does not "scorch" the air or reduce the humidity so strikingly as a furnace may. (2) The boiler room can be installed either in the school building proper or in a detached building even at some distance without serious loss in delivering the heat to the various rooms. (3) The radiators can be grouped into one unit or various units and readily proportioned to meet demands. (4) It can be utilized to introduce warmed fresh air into the schoolroom with or without a system of ducts from the basement.

For example, many devices have been developed to install coils beneath windows or along outside walls, and, through an opening below, to allow the fresh, cold air to circulate about the coils and pass directly into the room. Where they are connected with some mechanical system of ventilation they can be grouped into chambers in connection with the ducts directly below the rooms they serve, and in this way the heat units demanded can be easily computed and applied. (5) It is more efficient in cold climates for the reason that it can be used in any combination desired, and can be expanded as exigencies demand. This of course is true only if adequate boiler capacity is installed.

There are some disadvantages in steam heating, and among these the following may be mentioned. (1) It is expensive in installation, and, if not handled by experienced mechanics, it is an expensive system to keep in repair. (2) It is not well suited to mild climates, for it is slow to heat and slow to cool. Hence it is wasteful and not sufficiently responsive for those climates where a little heat is needed in the morning and none for the rest of the day, or where a slight, steady heat is needed all the day. (3) There is always some danger in steam boilers, especially in high pressure boilers. They need constant attention, and demand a skilled mechanic to manage them economically and safely. (4) In cold climates during the winter months, fires must be kept going day and night and during holidays as well, in order to prevent the pipes from bursting. (5) It seems difficult to adjust steam radiators so as to prevent the pounding noises occasioned by the water from condensed steam coming into conflict with circulating steam. This difficulty has been much reduced in the past few years, but it is not yet perfected.

On the whole steam heating seems to be the most satisfactory for cold climates, and is being largely used in the more temperate regions. The business of the installation of a steam heating system demands technical knowledge, and boards of education will always save money by employing an expert engineer who knows school demands, as well as the technique of his profession.

*Hot Water System* — The system of heating by hot water has not been used extensively in the schools of this country, though under favorable climatic conditions it is in certain respects well adapted for this purpose. In England it is more often used, and in that climate, save in extreme weather, has been found satisfactory. The advantages of a hot water system may be stated as follows. (1) It can be used, especially when supplied with a pump to facilitate circulation, in mild weather, without overheating and undue use of fuel. (2) It does not require such constant attendance as a steam heater, nor does it demand the technical ability to supervise. It is safer than steam, and

is not subject to such rapid fluctuations as other systems (3) It is ordinarily noiseless, and furnishes an acceptable quality of heat (4) It can be delivered a long distance from a central heating source at comparatively slight loss in temperature, and for this reason it often lends itself to great economy of fuel and service by the use of one central heating station for several buildings This point is worth considering because of the probable future tendency to group a number of school buildings together in suburban districts, where playgrounds, fresh clean air, and surcease from noise are possible

On the other hand, it has some distinct disadvantages (1) It seems to require more care to prevent leaks, especially when direct radiation is used in tall buildings and demands exacting attention in cold weather to prevent the pipes from bursting (2) It is generally less quickly effective than other systems, and, unless a large amount of radiating surface is furnished, it will not satisfy the demands for heat in very cold weather (3) It requires a greater superficial area or radiating surface to afford the same amount of heat than a steam heating system, and hence, where space must be economized either in basements or schoolrooms, this is a distinct disadvantage (4) Most engineers claim that it requires "more careful installation, and nicer calculation of the sizes of piping" than is required for steam heating

Owing to the fact that the amount of humidity associated with the air has a direct influence on the temperature demanded for comfort in schoolrooms, those in charge of modern school buildings, especially in the larger cities, have found it not only more wholesome to wash the air of dust and soot, but a matter of economy during cold weather because of the added moisture thereby introduced

It will be readily admitted by all that colds and bronchial affections are much more generally common in winter than summer This is not because disease germs are specially rampant in winter, but because the protection afforded by the mucous secretions of the air passages is reduced by the more rapid dissipation of this moisture by the dry air breathed in winter (See COLDS) The spaces between the molecules of cold air are restricted and hence the possible amount of water vapor occupying them is much smaller than that possible in the case of warm and hence expanded air When cold air is heated to the temperature required for the schoolroom, necessarily the percentage of saturation is greatly reduced Such air when breathed readily and quickly absorbs a great amount of moisture from the air passages Warm dry air is greedy, so to speak, for water vapor, and will also quickly absorb moisture from the skin and render the body harsh and dry But as a result of this evaporation the temperature of the body is lowered, for it is a principle of physics that a

body losing moisture through evaporation is thereby lowered in temperature To counteract the feeling of chill thus produced an abnormally high temperature must be maintained If, however, after the cold air has been heated it be driven through sprays of water, or be made to impinge on or pass through water-soaked screens of coarse cloth or porous material, it will acquire a higher percentage of saturation, and when passed into the schoolroom will not absorb an undue amount of moisture from the bodies of the children Hence the chill mentioned above will not be produced, and a lower temperature will satisfy Some estimates show that at least 10 per cent of the cost of fuel will thus be saved in very cold weather, and in addition better hygienic conditions will be furnished Many devices and appliances have been designed to secure this humidity and at the same time wash the air of dust and soot One of the latest and most promising methods devised for this purpose consists in what is called an air washing and cooling fan By this method "the air is forced through several successive layers of close-meshed wire screen, over which and through which water flows rapidly and in large quantities," and by the use of other means not necessary to specify here, the fan serves a triple purpose of an propeller, air washer, and humidifier

**HEBREW UNION COLLEGE, CINCINNATI, O** -- A theological seminary established in 1875 for the training of rabbis and teachers in the principles of Reform Judaism. A preparatory department of high school grade and

a 'Teachers' Institute are also maintained. The entrance requirements to the collegiate department are the same as those for the University of Cincinnati. The degree of Rabbi is conferred on candidates who fulfill the requirements and possess a degree equivalent to the A.B. of the University of Cincinnati. The College also confers the degree of Doctor of Divinity. There is a faculty of eight members.

#### HECKER, JOHANN JULIUS (1707-1768)

— A German educator, the father of the "Realschule," was born at Weiden on the river Ruhr, in what is now the Rhine province. His father and grandfather were schoolmasters, and he was educated in his father's school up to his fourteenth year, when he entered the gymnasium of the neighboring city of Essen. The rector of this school was a pupil of A. H. Francke (*q.v.*). In 1726 Hecker went to the University of Halle and, for a short time at least, came himself under the influence of Francke. He studied not only theology and philosophy, but attended also lectures on medicine and natural science. In 1729 he was appointed teacher of the "Paedagogium" in Halle, one of the schools founded by Francke, where for six years he taught all sorts of subjects, from Hebrew and the classics to chemistry, anatomy, and physiology. He also published a textbook of anatomy, one of physiology, and an introduction to botany. In 1735 he was called as pastor and school inspector to the military orphanage at Potsdam, where he attracted the attention of King Frederick William I. In 1739 he became the pastor of the new "Dreifaltigkeitskirche" (Trinity Church) in Berlin, a position in which he remained until his death. He first improved the elementary schools belonging to his parish, procuring the necessary means for this work through a school lottery, the shares of which were bought by people in different parts of Germany. In 1747 he opened a new kind of school, which was destined for the education of boys who were to be prepared for practical life. This school, which he called "Ökonomisch-mathematische Realschule" (now the Kaiser-Wilhelms-Realgymnasium), must be regarded as the mother institution of the whole system of modern (as distinguished from purely classical) secondary schools (Realgymnasien and Oberrealschulen) in Germany. He also did much for the training of teachers of the rural schools. The "General-Landschul-Reglement," the first general school law of Prussia, issued by Frederick II in 1763, was to a great extent Hecker's work.

#### HEDDING COLLEGE, ABINGDON, ILL.

— A coeducational institution founded in 1856

under the auspices of the Central Illinois Conference of the Methodist Episcopal Church. Academic, collegiate, music, and oratory departments are maintained. The entrance requirements are equivalent approximately to 15 points of high school work. The college grants the degrees of A.B., B.S., and Ph.D. The faculty consists of thirteen professors.

**HEDGE, LEVI** (1766-1844) — Educational writer and college professor, was graduated at Harvard College in 1792. He was tutor and professor in the college from 1810 to 1830. Author of *System of Logic* (1818), *Mental Philosophy* (1827), and other educational works.

W S M

**HEDGE-SCHOOLS** — A term applied originally to those schools which sprang up in Ireland as a result of the Penal Laws (1704-1728) by which no Catholic was allowed to give or receive education or to go abroad for purposes of study on penalty of a fine of £100, while children so educated could not inherit property in Ireland or England. A result of these measures was that secret schools arose in which priests and others taught as much as was possible under the circumstances. "On the high-ways and on the hillside, in ditches and behind hedges, in the precarious shelter of the ruined walls of some ancient abbey, or under the roof of a peasant's cabin, the priests set up schools and taught the children of their race" (McCarthy, p. 13). In this way the national cause and national existence was kept alive. The term, however, soon came to denote any kind of a poor school, and so Thackeray calls Paddy Byrne, Goldsmith's teacher, "a hedge-schoolmaster." In Germany the identical term *Heck-* or *Heckenschule* in Hesse is the equivalent of *Winkelschule* (*q.v.*). In medieval France unlicensed schools were known as *Écoles buissonnières*.

**HEDONISM** (ἡδονή, pleasure) — A term used to denote theories that make pleasure either the end, or the standard of intentional or conscious activity, moral behavior included. The ancient and the modern theories grouped under that name are, however, more widely different from each other than their common name would indicate. Ancient hedonism is associated with Epicureanism. Its chief motivation was revolt, on the one hand, against the moral theories which made virtue consist in fitting into the existing social order by performing the duties appropriate to the status in which a person found himself, and, on the other hand, against the theories which gave morals a purely rationalistic cast, basis, and aim. As against the first, Epicurean hedonism taught the advisabil-

ity of abstinence, as far as possible, from civic life, and the cultivation of voluntary associations based on congeniality and friendship. As against the second, it emphasized the importance of the feelings, and of cultivating the various types of enjoyment naturally accessible to the individual. Contrary to the usual belief, it taught not surrender to appetite, but moderation of desire, on the ground that excessive desire was fatal to happiness. Ancient, like modern, hedonism was naturalistic in tone, but here again the motive was different, ancient hedonism being convinced that supernaturalism tended to fear of death and of the intervention of the gods, and hence was detrimental to a life of serenity and contentment.

Modern hedonism, in its influential forms, has been associated with an empirical philosophy and with utilitarianism. Its chief object has been to set up a concrete standard for measuring the worth of acts, their consequences in the way of pleasures and pains produced. Its interest was not in outlining an agreeable mode of life, remote from strife and disturbance, but the discovery of a scientific mode of estimating right and wrong methods of action. Of the conscious search for pleasure it has made little, generally holding, in fact, that happiness is best attained when not consciously aimed at—the so-called hedonistic paradox. In its most important representatives—as Bentham and the Mills—it has been more interested in the development of methods for judging the effects of legislation and administration, civil and penal, by tracing their effect among the pleasures produced and the pains entailed upon the masses affected by them, than in elaborating a code for right action in private life.

As a moral system, hedonism has had little direct influence upon educational theory or practice. Matters of pleasure and pain are, however, so closely connected with the motivation of conduct that it would not be difficult to trace an implicit hedonism in the use made of rewards promised and punishments threatened as motives to studious behavior. Asceticism, moreover, is a kind of inverted hedonism, involving the notion that man is so naturally prone to pleasure-seeking that the agreeable must be shunned as a temptation to evil. Ascetic notions underlie many educational ideas and procedures, especially those that cluster about the notion that there is something disciplinary and moralizing in tasks and exercises in the degree in which they are disagreeable (see **FORMAL DISCIPLINE**).

**HEGEL, GEORG WILHELM FRIEDRICH** (1770–1831) — Born at Stuttgart and died at Berlin. He was the son of a secretary in the revenue office of the kingdom of Württemberg, and received a good education extending over eighteen years. With the purpose of pursuing theological studies, he attended the University of Tübingen (1788–1793), but, finding the prescribed theological and philosophical courses both dull and unfruitful, he devoted most of his time to classical and historical literature. His university certificate stated him to be of good ability, but of middling industry and knowledge, and especially deficient in philosophy. Six years (1793–1801) were passed as a private tutor, first in Bern and later in Frankfurt.

His career as a university teacher began in Jena (1801–1806) as *Privat-docent*. Later he became professor extraordinary. His first important book, *Die Phänomenologie des Geistes*, which he characterized as his “voyage of discovery,” was written here. The Battle of Jena interrupted the work of the university, and Hegel spent a year at Bamberg as a newspaper editor. Being appointed by Niehammer as professor of philosophy and rector of the new gymnasium at Nuremberg, a school of nearly 200 boys, he passed eight years (1808–1816) as a successful secondary teacher and headmaster. Hegel believed that classical studies formed the only sure basis for later intellectual work and development. At the same time he readily seized every opportunity for widening the curriculum and developing varied interests in the pupils. Military drill was introduced, and a school library and museum were started, to which parents and friends made gifts from time to time. In 1811 he married Marie von Tücher. One of his two sons, Karl, afterwards became professor of history at Erlangen. In addition to his work in the gymnasium, he wrote and published his greatest book, *Wissenschaft der Logik* (1812–1813, 1816).

His university career was resumed when he accepted the chair of philosophy at Heidelberg in 1816, declining calls at the same time to those of Berlin and Erlangen. He remained here two years, writing the *Encyclopädie der philosophischen Wissenschaften im Grundrisse* (1817). In 1818 he accepted the second invitation to the chair of philosophy at Berlin, made famous by Fichte (*q v*). His reputation was steadily growing, and he gathered round him a band of optimistic students and disciples. The *Grund-*

*Enzyklopädie der Philosophie des Rechts* appeared in 1820. His time at Berlin was given chiefly to teaching. His lectures on aesthetics, philosophy of religion, philosophy of history, and history of philosophy were published posthumously from his notes and those made by his students. In 1830 he was elected rector of the university. He died suddenly from cholera in 1831. "His philosophy may well be called the Prussian state philosophy during the years 1820 to 1840. It was the philosophical system officially acknowledged by the Ministry of Education" (Paulsen).

*Hegel's Philosophy* occupies a distinctive place in modern thought. The great German idealistic movement which, beginning with Kant, was developed in different ways by Fichte and Schelling reached its culmination and most complete presentment in the writings of Hegel. These philosophers all held that the universe becomes intelligible only as we adopt a spiritual interpretation. Benefiting as it were by the efforts of Fichte and Schelling to overcome the apparent dualism in Kant, Hegel became an evolutionist as well as an idealist in philosophy. The two worlds of nature and spirit are necessary to each other. The true meaning of life can be found only in the idea of progress or development. The essential condition of real progress is freedom. The solution of the problem becomes his doctrine of progress by antagonism — the necessity of two opposites and of a third which ever unites them on a higher level. This reconciliation of opposites is his key to evolution, — the only method of recognizing unity amid diversity. This position was reached only as the result of his development. He came to see that life is a process, that spirit must pass through many stages before it realizes itself, and that it is necessary to distinguish the stages of development from those of attainment. To attain self-realization, the Divine Unity must manifest itself in and through the many. And the many ultimately arrive at true freedom by learning to relinquish a lower form of freedom for the sake of a higher. One must learn to lose one's life in order to find it again at a higher level.

*The educational views of Hegel* follow directly from his philosophical theories. He wrote no separate treatise on education, but his views appear in passages in his philosophical writings, chiefly in the *Philosophy of Right*, where the sociological aspects of education are presented. The school addresses delivered while at Nuremberg also throw light on his theory and practice of teaching.

According to his idealistic view of evolution, the human stage is the most critical in the process. If man is to rise to a higher level of life, he must reconcile nature and spirit as fighting in himself for supremacy. The need of education appears related to this struggle, and arises from the fact that the child is but dimly aware of this necessity and ignorant of the true means of

progress. In the child nature is stronger than spirit, the life of the senses more developed than the life of thought. Until he has maturity for self-direction, the family or the state in its institutions must provide the necessary nurture, training, and discipline. Education is the joint business of the family and the community working together for a common end. Parents have charge of the early education of the child until he reaches school age, when he comes under the influence of the community acting through its civil servants, the teachers in public schools. In the cooperation of the family with the school the common aim to be kept in view is morality. The moral man alone is free, and freedom is the essential quality of spirit. A liberal education frees the mind from the bonds of nature so that it may identify itself with the universal, and thus attain the higher level of spiritual life.

In the first stage of this education the child takes small part. The demand is from without, and he obeys, "but through instruction and education his own inner powers are awakened and he becomes conscious that knowledge, morality, and religion belong to his own nature." At this point of awakening, or "new birth," usually occurring at the secondary school age, the educational process becomes critical. What Hegel calls the "centrifugal force of the soul" now comes into play. The desire for "self-estrangement" is natural and necessary, but the step must take place under the teacher's guidance. The pupil must be taken right out of himself and his natural surroundings and interests in order to live the life of imagination and thought, — to apprehend the universal. The classical histories and literatures offer the best means to this end. Greek and Latin (as dead languages) shut the door upon the everyday self, and the teaching of them should be directed to making the pupil share in the thoughts, feelings, and actions of the ancients. By learning to live apart from himself, he realizes in part the nature and value of moral relationships and the meaning of the State. At the end of the return journey from this self-estrangement, the pupil finds himself again, but now in relation to universal life. This defense of the classical curriculum is far more philosophical than the argument from formal discipline which had for some time been advanced by German teachers. Hegel naturally laid much stress on the importance of moral training and discipline. He urged the necessity of firm discipline and a moral atmosphere in the school. Punishment is the right of the transgressor, and must not be withheld. Both direct and indirect moral instruction are necessary. The former he himself gave in connection with lessons in religion and philosophy (set forth in the *Propädeutik*), the latter through the ordinary school subjects.

Hegel's influence on education was very great during the latter part of his life and for some time after his death. His disciple and biographer, Rosenkranz (*qv*), devoted extended

efforts to setting forth his educational views, and many of his students tried to work out the educational implications of his philosophy. Froebel's pedagogy obviously owed much to Hegelian influence. In more recent years there has appeared a revival of his influence in the educational thought of America and England

**HEGIUS, ALEXANDER** (?1433-1498) —

An early humanist schoolmaster who contributed largely to the humanistic revival in northern Europe. He was born in Westphalia, and taught at Wessel and Emmerich before he came to the scene of his greatest activity, Deventer (*qv*), in 1465, where he became headmaster of the school attached to the Church of St. Lebuin. The school flourished so greatly under his charge that at his death it numbered about 2000 pupils. He associated with himself Sinthus, who probably influenced Erasmus (*qv*), and several members of the Brethren of the Common Life (*qv*). He himself appears to have taught the upper classes. Erasmus says that "from Hegius and Sinthus the school drew some savour of the true letters." And in a letter Hegius says, "All learning is futile which is acquired at the expense of piety." At the age of forty Hegius studied Greek under Rudolph Agricola (*qv*). The humanistic spirit was introduced into the school, and many of the northern humanists, *e.g.* Buschius, Murmellius, and others came under its influence. Hegius wrote several dialogues, which were published in 1503. They are catechisms on different topics, *e.g.* *De scientia quod eo scitur*, *De rhetorica*, *De moribus*. In the *De utilitate Græci* he insists on the value of a study of Greek for all departments of learning, "for to the Greeks we are indebted for everything."

**HEIDELBERG, THE RUPRECHT-CARL UNIVERSITY OF.** — The University of Heidel-

berg, in the Grand Duchy of Baden, is the oldest university and to this day one of the most renowned institutions of higher learning in the German Empire. It was founded upon the model of the University of Paris by the Elector Rupert I of the Palatinate in 1386, the Papal Bull of Urban II being dated Oct. 23 of the previous year. At this time Prague, established in 1348, and Vienna, established in 1365, were the only universities in German-speaking territory. The work of organization fell largely to the first Rector of the university, the Dutchman Marsilius von Inghen. Although students flocked to the four faculties of the new institution in considerable numbers at the very start, the university did not reach the period of its greatest renown until the latter half of the sixteenth and the beginning of the seventeenth century, during which time it was the center of Humanism and Reform in Germany — this in contradistinction to the Catholic tendencies that had been strongly emphasized in the earlier days. This era of prosperity, however, was soon followed by one of stagnation, as the result of the Thirty Years' War and the devastation of the Palatinate by the French in 1689 and 1693, the university being compelled to close its doors from 1631 to 1652 and again from 1693 to 1700. A number of the fugitive professors continued their lectures at Frankfort from 1694 to 1698 and at Weinheim for two years subsequent. During the eighteenth century the institution was in the hands of the Catholic counter-Reformation, and was on the verge of extinction as a result of the severe blows dealt the town during the revolutionary upheavals at the close of the century. Not until Heidelberg with the Palatinate on the right bank of the Rhine was incorporated with Baden in 1803, did the university regain its former prestige, the elector Charles Frederick being responsible for a thorough reorganization of the seat of learning. The university to-day consists of five faculties, viz. theology (Protestant), law, medicine, philosophy, and pure science, the last mentioned having been made independent of the faculty of philosophy in 1890. A faculty of political science, established in 1803, was incorporated with the faculty of philosophy nineteen years later. The first psychiatric clinic associated with a university was organized at Heidelberg in 1827, and one of the first university botanical gardens was laid out in connection with the faculty of medicine as early as 1593. The university also possesses an institute for cancer research (1906) under the directorship of Professor Czerny. A radiological institute was founded in 1909, and in the same year the Heidelberg Academy of Science was established. Among the eminent teachers who have been connected with the university may be mentioned Hermann Helmholtz in physiology, Bunsen in chemistry, Kirchhoff in physics, Hegel and Kuno Fischer in philosophy, Boeckh

in classical philology, Schlosser, Gervinus, von Treitschke, and Winkelmann in history, and Windscheid and Mittermaier in jurisprudence. The administration of the university is in the hands of a prorektor, the reigning Grand Duke of Baden holding the office of Rector.

The library of the University of Heidelberg has had an interesting history, going back to the earliest days of the institution. It increased steadily in importance until the beginning of the seventeenth century, when it was generally regarded as one of the leading collections of the world. After the capture of Heidelberg by Tilly during the Thirty Years' War (1622), the most valuable portion of the library, the famous *Bibliotheca Palatina*, which included no less than 3527 manuscripts, was presented by Maximilian I of Bavaria to the Pope and removed to Rome, and a little later a somewhat similar fate overtook the newly gathered collection. Several of the manuscripts transferred to Rome in 1623 were restored in 1814, and later all of the old German manuscripts were returned. The present library, which moved into a new building in 1905, is only about a century old; it contains about 400,000 bound volumes, 200,000 dissertations and pamphlets, over 3000 papyri, 3200 documents, and 4000 codices, including the famous *Manesse Liederhandschrift* from the beginning of the fourteenth century. The latter is the richest collection of the kind in existence, consisting of 428 folio leaves, and containing over 7000 stanzas, chiefly South German lyric poems, by 141 authors, and 137 full-page illustrations.

In attendance Heidelberg is exceeded by ten German universities, its total enrollment in the winter semester of 1909-1910 being 2089 (194 women), this number including 155 auditors (52 women). Of the matriculated students almost half are found in the faculties of philosophy and pure science, viz. 954, medicine with 513 coming next, then law with 405, and finally theology with only 62. In the summer semester of 1910 the University of Heidelberg enrolled 2552 students.

**HEIDELBERG UNIVERSITY, TIFFIN, OHIO**—A coeducational institution founded in 1850 by the Ohio Synod of the Reformed Church. It maintains an academy, college, and departments of pedagogy, commerce, music, art, and elocution. The entrance requirements are fifteen units. The degrees of A.B., B.S., Ph.D., and B.L. are conferred on

the completion of appropriate courses. There is a faculty of twenty-eight members.

#### HEIGHT AND WEIGHT OF SCHOOL CHILDREN.—See GROWTH.

**HEINICKE, SAMUEL** (1727-1790) — The pioneer of the German system of deaf-mute instruction; was born of a well-to-do peasant family in Nautschütz, near Weissenfels, Saxony. He attended only a village school, but at an early age showed a great love of books, which he had to satisfy in secret against his father's wishes. At the age of twenty-three he ran away from home to escape a marriage into which his father wanted to force him, and enlisted in the electoral body guard at Dresden. There he found time to pursue his studies in Latin and French, and later on even to give private lessons. In 1754 a deaf and dumb boy was brought to him, and he attempted to teach him to speak, using the method given by Amman (*qv*) in his book *Surdus loquens* (*The Deaf Speaking*). Wishing to devote himself entirely to teaching, he asked for his discharge from the army, but the outbreak of the Seven Years' War prevented the granting of his request. Having been taken prisoner by the Prussians in the battle of Pirna, he succeeded in making his escape and went to the University of Jena, where he enrolled as a student in 1757. Soon after, however, a Prussian recruiting party passed through Jena, and Heinicke, to avoid recapture by them, fled to Hamburg, where he became the secretary of the Danish ambassador Count Schimmelmann. Through the count's influence he obtained a position as a teacher and organist in the village of Eppendorf, near Hamburg (1769). There he renewed his interest in the training of deaf and dumb children, and acquired such fame that he was recalled to Saxony, where, in 1778, he opened the first German institution for deaf-mutes. In contrast with the Abbé de l'Épée, whose school for deaf-mutes, the first in the world, had been established in Paris in 1760, Heinicke instructed his pupils not in the gesture language, but in lip-reading and speaking. (See **DEAF, EDUCATION OF THE**, II, p. 257.) His object was to restore the deaf-mutes to society by making them use and understand the common spoken language.

In 1780 he published a book *Über die Denk- art der Taubstummen* (*On the Mode of Thinking of Deaf Mutes*), in which he made a violent attack on the Abbé de l'Épée. From this arose a rather bitter controversy on the merits of the different methods of deaf-and-dumb training, which he carried on for the rest of his life.

Heinicke's ideas on general education show that, apart from his special vocation, he possessed remarkable pedagogic insight. In some respects he even anticipated Pestalozzi. He called upon the clergy to take the initiative in the improve-

ment of the rural schools. He advocated a phonetic method of teaching reading, and insisted on giving children clear sense perceptions before abstractions. His vigorous insistence on the oral teaching of deaf-mutes has caused this method to prevail in Germany and most of the other countries of Europe.

**HELMSTEDT, UNIVERSITY OF, GERMANY** — The last of the important universities which were due to the influences of the Reformation. Opened originally in 1571 as a *Padagogium Illustre* at Gandersheim by Duke Julius of the House of Brunswick-Wolfenbüttel, it was removed to Helmstedt in 1574, and an imperial charter was obtained in 1576 raising the institution to the status of a university. The university was organized on plans drawn up by a disciple of Melancthon with faculties of theology and philosophy. Students had to subscribe to the Augsburg Confession. For some time the university met with great success, especially in its theological faculty. In the eighteenth century there were professorships in the humanities, Hebrew, mathematics, natural science, logic and metaphysics, law, politics, and history. From 1779 to 1810 an important philological-pedagogical institute was maintained at the university, organized by Frederick August Wiedeburg. In connection with this seminar, teaching practice was obtained in the *Padagogium*. The university was closed in 1809, probably through the rapid rise of its neighbor, the University of Göttingen (q v).

**HELPS, SIR ARTHUR** (1813–1875) — Clerk to the English Privy Council and adviser to Queen Victoria, at whose request he prepared the Prince Consort's speeches for the press. He was a prolific writer on a variety of topics, among them *Conquerors of the New World* (1848) and *Spanish Conquest in America* (1855–1861). His *Friends in Council* (1847–1859), a collection of essays and dialogues, contains an essay on Education which "has told us more truth about education in a few pages than one sometimes meets with in a complete treatise" (Quick). Government provision of education is commended if it does

not interfere with private schools. The end of education is happiness or contentment of the individual. Helps considers education under four heads: (1) religious, which he recognizes must be sectarian, but should not exclude tolerance and open-mindedness, (2) intellectual, which should be a training in mental power through emphasis on accuracy, attention, logic, and method, and many-sided pursuits as a general basis in an age of increasing specialization; (3) moral, in which the child shall be trained to moral independence by good examples; (4) physical, including ventilation and food, clothing, and bodily freedom. The education of women should be like that of men for the improvement of mental power, without any fear that similar education would lead to similar results in the two sexes.

**HELVETIUS, CLAUD ADRIEN** (1715–1771) — Son of John Claud Adrien Helvetius, and descended from a famous family of physicians. He showed small aptitude for study in early life, but was fond of reading, and, in course of an apprenticeship in finance, amused himself by writing verse and cultivating social graces. Into mathematics and poetry he made numerous excursions, without, however, achieving marked distinction, while in philosophy his famous work, *De l'Esprit* (1758), consumed the greater part of seven years of work.

His reputation as a thinker rests on the work above referred to, which created a great furore when it appeared, though its merits do not warrant the attention it received. The chief points which he set himself to illustrate and enforce are these: (1) all the mental faculties are reducible to physical sensation, sentience, or feeling, (2) self-love, or self-interest, is the motive of all judgment, action, and affection, there is no such thing as liberty of choice or abstract right, custom (i.e. practical advantage) explains all our particular ideas of justice and moral worth, (3) the differences of personality or character among men depend on the inequalities of intellectual attainment due to education, and inasmuch as all are equally susceptible of education, we owe all we are to that cause, (4) all talent, therefore, all taste, imagination, and genius, are only particularly successful forms of the chances which enable some to gratify their instincts by means of education more easily than others. A work entitled *De l'Homme, de ses Facultés intellectuelles et de son Éducation*, was discovered after his death among his pa-

pers and published in 1772. It forms a sort of supplement to *De l'Esprit*.

Diderot (*qv*) had no difficulty in refuting these positions, which, as one critic has said, were all contradicted by the actual practice and life of their author. On two points his posthumous essay touched directly on education, namely in Sections I and X, where he expatiates, in a paradoxical way, on the potency of education and on the necessity of making all education, including that of the church, subject to the civil power. His doctrines, however, have not stood the test of experience and criticism, indeed, they are now thoroughly discredited. Legislation, upon which Helvetius relied to act the benevolent rôle of securing all the moral and educational goods for the people which they needed to make them contented and happy, has not proved the panacea he expected it would. Besides, he here argues in contravention of his fundamental theory that self-love is the motive of welfare. "The substance of what he proposes is better than the grounds on which his proposals rest" (Ueberweg). H D

**HENDERSON COLLEGE, ARKADELPHIA, ARK**—A coeducational institution established in 1890 under the auspices of the Methodist Episcopal Church, South. Academic, collegiate, music, and art departments are maintained. Fourteen units of high school work are required for entrance to the college courses which lead to the degree of A B. There is a faculty of seventeen instructors.

**HENDRIC COLLEGE, CONWAY, ARK**

A coeducational institution opened under its present title in 1889 under the auspices of the Methodist Episcopal Church, South. An academy is maintained in addition to the college. The requirements for admission to the college are fourteen units of high school work. The college offers two groups of studies, classical and Latin-scientific, both leading to the A B degree. There is a faculty of eleven members. The college has a productive endowment of \$300,000, and a plant valued at \$100,000.

**HENKLE, WILLIAM DOWNS (1828-1881)**

—Superintendent of public schools, received his school training in the Springfield (Ohio) High School and Wittenberg College. He was principal of secondary schools in Ohio (1848-1854), superintendent of schools at Richmond and Salem, Ohio (1854-1864), and State Superintendent of Public Instruction in Ohio (1864-1871). Author of a series of mathematical textbooks. W. S. M.

**HENRY VI, KING OF ENGLAND (1421-1471)**—Henry VI, far more than Edward VI, deserves to be remembered as the founder of English schools and as an eminent promoter, though by no means creator, of English education. Like his successor, the boy-king suffered personally from overeducation. On June 1, 1428, his education, which since 1424 had been in the hands of Dame Alice Boteler, was transferred from the lady to Richard Earl of Warwick and Albemarle. "Whereas," says a writ of Privy seal in French, "it is expedient that in our youth we should be taught and indoctrinated in *bons meures lettrure langage e norture et courtoisie et autres vertus et enseignements*," which articles in English annexed translate as "nurture, lettrure (*i.e.* grammar), language and other manere of connyng," and, above all, "*de nous faire traire a vertues et eschuer vices*, to draw us to vertues and to eschewing of vices." Therefore the earl was given power "if we estrange ourselves from learning or do wrong to reasonably chastise us as other princes of our realm and of other realms are accustomed to be chastised." He must have found the young king a difficult pupil to flog, as four years later, on Nov. 29, 1432, when the king was eleven years old, the earl laid before the Council a series of articles. In one he said that the King "is grown in stature of his person and also in conceit and knowleche of heigh and royal autoritee and estat, the which naturally causen him, and from day to day as he groweth shall causen him more and more to grucche [grudge] with chastising and to lothe it." So he asked, not to leave off chastising him, but for the support of the Council in doing it, and in appeasing any indignation the King might feel against him for doing it, with power to remove those whom he knew "at part and in prive not hering ye said Erle" who had "stured" him "from his lernyng." He obtained a promise that the whole Council would tell the King that it was their advice that he was chastised for his "defaultes," so that "for awe thereof he forbere ye more to do mys and entended ye more busly to vertue and to lernyng." The Council agreed. That Henry did not resent the Spartan training which Warwick thought necessary is shown by his making his quondam tutor and chastiser Duke of Warwick, the first duke in England not of royal blood. His experience of the Palace School, being brought up with the young nobles, an arrangement almost certainly made in imitation of the Casa Giocosa established by Gonzaga, the Marquis of Mantua, for his son and his nobles' children under Vittorino da Feltre in 1423, was no doubt largely responsible for Henry's foundation of Eton College (*qv*) within view of his birthplace and favorite residence at Windsor Castle, and its including, besides the original twenty-five, afterwards seventy scholars, twenty sons of noblemen. Eton, though by no means the first or the last of Henry's educational

## HENRY VI

foundations, was the greatest and that to which he gave most personal attention. One of the earliest fellows of Eton, John Blakman, records how he took special care in the selection of the fellows, and how he always noticed the boys when they came for leave out to any of the court at Windsor, giving them a "tip" or "small present of money" and telling them to be good boys. His father, Henry V, had designed to endow a college at Oxford greater than all the existing colleges, for the "Seven Liberal Sciences" out of the Alien Priorities (*qv*), suppressed because of their supplying sinews to French houses during the Hundred Years' War. Henry, or rather the Duke of Bedford, the Regent of France in his name, had already established a university at Caen in 1432, at first only for civil and canon law, which was not allowed at Paris, but extended after the English were expelled from Paris to theology and medicine, in the hope of keeping the subjects of the English King away from Paris. In 1441 another university was established for Henry's southern dominions at Bordeaux. The royal college of St Nicholas, commonly called King's College at Cambridge, was provided by Henry's own act on Feb. 12, 1441, and built with his own money at Cambridge for a rector and twelve fellows, to be later enlarged to a provost and seventy fellows and brought into organic connection with Eton in 1443. In 1446 he founded a second college at Cambridge, called St. Bernard's, for a provost and four fellows, changed in the following year into the Queen's College of St. Margaret and St. Bernard, with his wife Margaret of Anjou as petitioner, patroness and foundress, now called Queens' College because refounded and enlarged in 1475 by Elizabeth, queen of Henry's "traitor" Edward IV. The College of God's House at Cambridge was absorbed into Christ's College, founded in 1440 on a petition to Henry, to provide learned masters for grammar schools, the first secondary training college created *ad hoc* was perhaps inspired by him. But the great Oxford College of this epoch, Magdalen, owes its origin to Henry, and it was founded in 1448 by William of Waynflete, whom he had taken from the headmastership of Winchester to be provost and organizer of Eton, and then made Chancellor of the Kingdom and Bishop of Winchester. Waynflete improved on the example of Henry and of Wykeham by attaching to his college not merely one school, now known as Magdalen College School, at Oxford, but another at his native place, Waynflete in Lincolnshire. Another college at Oxford, Oriel, founded a century earlier, received augmentation from Henry in the shape of scholarships for boys of Eton and also in the attachment of similar scholarships of the new school founded by him in London, in St. Anthony's Hospital in Threadneedle Street, that "alien priory" being converted into a

## HENRY, JOSEPH

secular hospital, and new endowments for the school planted in it being given in 1441. Henry's example was followed by the foundation of ten colleges and schools at Newport Salop, by Thomas Draper in 1442, by Archbishop Kemp in Wye College, Kent (now an Agricultural College) in 1447, by augmentation of Fotheringhay College, Northamptonshire, by Richard Duke of York in 1440, by the college of chantry at Towcester, Northamptonshire, by Archdeacon Sponne Sept. 4, 1447. There were also founded the gild grammar school at Deddington in 1445, the chantry grammar school at Wokingham, Berks, by Adam de Moleyns, Dean of Salisbury, in the same year, the chantry grammar school of Robert Gryn timer, notable for being "half-free," at Newland, Gloucestershire, in 1446, the gild school at Clare, Suffolk, by Richard, Duke of York, in the same year, the double chantry schools, of grammar and song, at Alnwick by the Earl of Northumberland, and his brother William of Alnwick, Bishop of Lincoln, in 1445; the chantry school at Great Baddow, Essex, in 1449, the gild school at Chipping Norton in 1451. The troubles that then ensued, arising from Henry's melancholic insanity and the Wars of the Roses, cut short the progress of education and the foundation of colleges and schools for twenty years. But even so the educational record of Henry VI's reign eclipses that of any other reigns but those of Edward III and Henry VIII, and Henry's own personal share in it was greater than that of any English king.

**HENRY KENDALL COLLEGE, TULSA, OKLA** — A coeducational institution established originally at Muskogee, Indian Territory, in 1894. It was moved to its present location in 1907, and is under the auspices of the Presbyterian Synod of Oklahoma. Academic, collegiate, music, art, and expression departments are maintained. The entrance requirements are sixteen units. Classical and scientific courses are offered, leading respectively to the A.B. and B.S. degrees, and preparation is given for the study of medicine, law, and teaching, as well as the ministry and mission work. There is a faculty of twelve members.

**HERACLITUS** (c. 535–475 B.C.) — Known as “the weeping philosopher,” in contrast with Democritus, “the laughing philosopher.” He was a pupil of Xenophanes, and, like him, was interested in the physical explanation of the universe. His fundamental teachings were that fire is the primordial element, that all material things are in a continual flux and reflux of becoming and perishing, and that the harmony and unity of nature consist in its multiplicity and diversity. His teaching was materialistic and pantheistic, and anticipated many of the conclusions of modern science and philosophy. He is regarded as the founder of metaphysics, and has been held in especial reverence by the Stoics and Hegelians. His school numbered many disciples, the chief of whom was Cratylus, the teacher of Plato. Of his work *On Nature* only a few fragments remain. W. R.

**HERBART, JOHANN FRIEDRICH** (1776–1841) — German educator and philosopher; born at Oldenburg, May 4, 1776. His father was a councillor, his mother an extraordinary woman who learned Greek with her son under his tutor in order to supervise his studies the more effectively. The boy Herbart was precocious and ambitious in his learning, devoted to mathematics, and talented in music. At eleven he began logic, and at twelve metaphysics, while the gymnasium of his native town, which he entered after he had already attacked these subjects under his tutor, provided him with additional opportunities for the study of his beloved philosophy and of physical science. From the gymnasium Herbart proceeded as a student to the University of Jena, there to fall under the spell of the

fresh and dominating thought of the idealist philosopher Fichte (q.v.).

The influence of Fichte upon Herbart was profound, but it was not long before the pupil departed from his master on the principles of idealism and freedom. Herbart came quickly to the conclusion that man is not free in the sense of possessing a principle independent of circumstances and environment, and reverted also to the doctrine of Kant, that behind and underlying the world of appearances there is a plurality of real things-in-themselves that are independent of the operations of mind upon them. Herbart thus became the founder of modern philosophical Realism, as contrasted with the Idealism which denied the existence of things-in-themselves independent of any form of consciousness. Broader and deeper grew Herbart's devotion to philosophy, but it soon became complicated with another interest, education. In 1796 Herbart left Jena to be tutor to the sons of the governor of Interlaken, a duty which he appears to have fulfilled with rare conscientiousness and skill. It was his own experience, coupled with his philosophical thought, that already suggested to him, first, the enormous importance of cultivating a many-sided interest, secondly the value of the *Odyssey* as the point of contact in the early fellowship between pupil and teacher, and thirdly the idea of a method that should combine education and instruction without the subordination of either motive to the other.

In 1799 Herbart paid a visit to Pestalozzi (q.v.) at Burgdorf, but in the same year decided to abandon his post as tutor, which various events had combined to render untenable, and to devote himself anew to philosophy with a view to teaching it in a university. At this time, too, he had thoughts of the reformation of schools, and wrote *Ideas for an Educational Curriculum for Higher Schools* and a criticism upon Pestalozzi's *How Gertrude teaches her Children*, and *Idea of an ABC of Sense-Perception*. The emphasis of Herbart at this time was especially upon the use of mathematical forms to correct the undisciplined observations of the eye.

In 1802 Herbart departed to Gottingen, where he received his degree of doctor and began to teach education and philosophy. Those were troublous times in Germany, but Herbart remained faithful to the intellectual life, and put forth work after work of so finished and original a quality that in 1809 he was paid the high compliment of a call to the chair of Königsberg, previously rendered so illustrious by Kant. At Königsberg Herbart developed his psychological theories and transferred his educational efforts from the speculative to the practical stage by the foundation of a pedagogical seminary. This institution developed into a training college and school in which the mathematical instruction was given by Herbart in person; but its activities were

unfortunately interrupted by the departure of its founder for Göttingen in 1833, owing to the hostility of the Prussian government of the day to democratic ideas and academic freedom. At Göttingen he continued to lecture and write on education and philosophy to within two days of his death.

**Herbart's Educational Views** — Herbart was convinced that, although many elements are spoken of as entering into the end or aim of education, yet its one and whole work may be summed up under the concept *morality*. Since the days of Kant, it was recognized that the first thought which this concept suggests is the good will. Herbart reacted against the current idea that this good will has only to express itself spontaneously in the pupil. On the contrary, he maintained, the good will may and must be cultivated in the child by the teacher. Morality is for the teacher a natural event, which has its causes like other natural events. This appeared to Herbart to rule out of court the idea of a transcendental freedom of the will which makes it independent of the causes acting upon it. "Not the gentlest breath of transcendental freedom must be allowed to blow through ever so small a chink into the teacher's domain." Herbart perceives that, if this be so, another ground than that which is generally accepted, that is to say, a ground other than either utility or external command, must be found for morality. He finds it in æsthetic necessity. We have an original, absolutely independent æsthetic judgment, self-evident, and of peculiar nature, which gives us the sense of duty. Education will attempt to properly exercise this judgment, and therefore cultivate the good will by a revelation of the whole known world and every known age. Full knowledge is thus the ground of virtue. Instruction will guide the two courses of knowledge and sympathy to the highest ground of their union.

**General Principles** — Herbart as a student of philosophy and history was thoroughly acquainted with the educational works of Locke and Rousseau. He regarded the ideas of Rousseau as theoretical and doctrinaire; those of Locke as worldly. Rousseau would educate a natural man, Locke a conventional man; but it would be as difficult to train a natural man as it would be for the natural man to live in actual society when trained, while the conventional education of Locke would involve too easy an acceptance of the life of the man of the world. "Conventional education seeks to prolong existing evils; 'natural' education means to repeat if possible from the beginning the succession of evils already overcome." The principal method of conventional education is intercourse by conversation and travel, of natural education experience; but the emphasis which Herbart believed to be the most important was on instruction.

Herbart was the first to perceive that education was thoroughly worthy to be a science of itself, and not a mere department of philosophy. Education had suffered, as medicine had suffered, by government as a remote and tributary province. It needed the eye of science and a psychology in which the total possibilities of human activity might be sketched out *a priori*. Nevertheless the individual can only be discovered by the educator, not deduced. The fundamental necessities in pedagogy are education through instruction, involving discipline (*Zucht*) as a part of itself and not as an external force, and science and mental force.

**Herbart's Use of the *Odyssey*** — Education through instruction, with morality as its aim, involves the presentation to boys of such men as they themselves would like to be. Yet this presentation should not be made sporadically, but in the midst of a long series of other means of education. It must not be spun out of the teacher's imagination, which is not ideal or poetic. The only place in literature where the ideal vehicle for the education of boys is to be found is the classical age of childhood among the Greeks. Here the *Odyssey* stands first; and again and again Herbart recurs to the *Odyssey*, which he actually used in this manner, at first as a tutor, and afterwards in the training college at Königsberg, as the fittest starting-point for school education. The *Odyssey* elevates the pupil without depressing the teacher, and assists the boy in his task of recapitulating the great development of humanity.

**Many-sidedness and the Method of Instruction** — Herbart perceived that the concentration which is the essential method of the cultivated man may become so exclusive as to falsify every other impression except that which is habitual. To avoid this danger, the educated mind should be many-sided. But can this be, without the destruction of the personality of the individual? Herbart was convinced that this opposition is overcome in the act of reflective thought, since the object reflected upon depends upon personal choice, while the power of reflecting comes largely through seeing many sides of a situation. Reflective thought is welcomed by the teacher; it is in fact his main reliance. The necessary steps in producing it in the pupil are according to Herbart's own analysis four — clearness, association, system, and method. The followers of Herbart have adopted these steps, now modified into five, as the formal basis which may ordinarily be used in the subdivision of a lesson period (*the formal steps of method*). According to this plan, the teacher at first assists the pupil to clearly distinguish his ideas, after which he presents the new material, which is subsequently associated and applied. Herbart did not distinguish the formal steps of method

with the precision and finality that have been claimed by his followers; on the contrary, the steps were to him the factors in the process of thinking rather than the logical subdivisions of a lesson period. The formal steps are useful, however, in many lessons whose primary object is to impart theoretical information; while the analysis at present most in favor is into preparation, presentation, association, generalization, and application.

*Interest.* — The place of interest in education had never been satisfactorily determined before Herbart, and his analysis, while not final, is still probably the best we have. Interest is the one emotion which assists rather than retards the operations of reason. It normally involves the process of observation, expectation, demand, and action. In general it depends upon knowledge and sympathy; that is to say, knowledge of the manifold, of its law, and its æsthetic relations, and sympathy with humanity, society, and the relation of both to the Highest Being.

Herbart perceived that the idea of many-sidedness, unless limited in some way, might lead the teacher to encourage a pupil merely to dabble in many external things. In order to prevent the loss of unity that would result from such a method, he preferred to recommend to the teacher the cultivation of an internal many-sidedness only, that is to say, a many-sidedness of interest. Interest is like desire, will, and the moral judgment in being opposed to indifference; but it differs from these faculties in that it does not control its object, but depends upon it. Interest can be controlled by the educator, because it depends on its object, which the teacher can determine at least in part. Through interest the teacher can control the allied processes of observation, expectancy, demand, and action. The teacher will not hesitate to control the interests of children.

*Instruction.* — Experience gives knowledge, intercourse gives sympathy; and to attempt to dispense with these factors in education would be to give up daylight for candlelight. But experience and intercourse are not in the power of the teacher, besides, they are often wearisome. Instruction is in his power, and need never be tedious. It penetrates more deeply into the mind than either experience or intercourse; and concentrates all the objects of human interest in the bosom of the young. To the pupil experience and intercourse should flow more fully from his teacher than from the life around him. "Instruction must universally point out, connect, teach, philosophize. In matters appertaining to sympathy it should be observing, continuous, elevating, active in the sphere of reality." Herbart was convinced that "filling the mind" is the first duty of the teacher, because it is the content of the mind that regulates behavior. In order to create a satisfactory mental con-

tent, instruction when analyzed should be found to have covered the fields of empiricism, sympathy with mankind, speculation, taste, sympathy with society, and religion.

*Character.* — The seat of character is the will, regarded not in its occasional moods of caprice, but in its firmer and more uniform operations. There is a difference between the will of a child previous to reflection and the will of a man after reflection. The former kind of will is more easily educated, while it still remains for the latter to give the ultimate settlement and sanction. It is characteristic of the will that it reappears as the same, as if it had a memory. Self-contemplation further develops and establishes this unity, and creates what is called principle. But principle can never fully include the objective parts of character, and consequently every character is more or less subject to inward conflict.

None the less, the foundation of the moral life is in "a sober, clear, firm, and determinate judgment." It is this alone which can be trusted to control action. For human activity depends in the first instance on the circle of human desires, which are indeed partly sensuous, but partly determined by intellectual interests. We cannot desire what we are utterly ignorant of. Great moral significance is therefore attached to the circle of ideas. "The circle of thought contains the store of that which by degrees can mount by the steps of interest to desire, and then by means of action to volition." By this route even moral training brings us back to the method of instruction. "Instruction will form the circle of thought, and the circle of thought the character." A firmly established circle of thought is essential to moral strength of character, and is generally preferable to an extreme mobility which tends toward the frivolous and the new. In a normal boy the strength of character which is a resultant of fixed ideas is not of a kind to oppose too strong a resistance to the ~~plant~~ power of education. The essential principle of Herbart's theory of education is the dependence of the character upon knowledge. "Great moral energy is the result of broad views, and of whole unbroken masses of thought."

*Discipline.* — "Direct action on the youthful mind with a view to form is discipline." Herbart viewed discipline as continuous treatment which does not ordinarily resort to rewards and punishments, but which does so only occasionally and then for emphasis. It must not be monotonous; it must cooperate in the formation of the circle of thought. It must involve mental as well as physical activity, for both are healthy; above all, it must involve the habit of work of every kind. Discipline will gradually disappear after the cruder forms of government have already been abandoned in relation to the child. It vanishes as the youth comes to the stage where he takes

over the control of his own education; while the work of instruction still goes forward to its goal in the formation of character

**Herbart's Philosophy and Psychology.** — In philosophy Herbart began as a disciple of Fichte, by whom he was greatly fascinated, but his independent and critical spirit soon caused him to abandon the extreme idealistic position and to return to the original theory of Kant. He accepted and developed the Kantian dualism between the real and the rational. Ultimate reality consisted for him in a number of reals which give rise to the world of appearances by their self-preservation against one another. The soul is metaphysically one such real, without parts or faculties, but its reactions for self-preservation give rise to the appearance of presentations which become clarified as ideas. The ideas act as forces, the mind itself is a series of masses of them, each mass rising or falling from the threshold of consciousness according to its groupings and consequent trains of association. It is characteristic of the psychology of Herbart that the unit of mental activity is the idea, so that will, desire, interest, and feeling are all of them grounded in some sort of intellectual activity. In this way the psychology of Herbart supports in the most logical manner his emphasis upon instruction and upon the importance of the circle of thought for the formation of character. The ideas, as it were, are at strife with one another for the possession of the foreground of consciousness. They resist one another, and in this act of resistance each is changed into an effort to present itself. When hindrances are removed, the ideas will present themselves. The implication of this theory of mental activity for education is the supreme significance of the formation of right, strong, unimpeded groups of ideas. For the ideas are regarded as combining with one another, or attacking one another, according to mechanical laws that are subject to mathematical determination, after the parallel of the laws that govern the interaction of molecules according to the atomic theory of chemistry.

Because of his elimination of innate faculties from psychology, his use of mathematical processes, his insistence upon the need of empirical studies of psychological fact, and his thoroughgoing associationism, with its necessary emphasis upon "apperception" (*qv*) and interest, Herbart is regarded as one of the greatest psychologists of modern times. Because of his critical ability and the lucid conscientiousness of his logical deductions, and because he led a reaction against metaphysical idealism, in which he has been followed by such philosophers as Beneke and Lotze (*qqv.*), he is equally preeminent among modern metaphysicians.

**Herbart's Educational Works** — The principal educational works of Herbart are *Ideen*

*zu einem pädagogischen Lehrplan für höhere Studien* (1801), an essay on Pestalozzi's *Wie Gertrud ihre Kinder lehrt* (1802), a criticism of Pestalozzi's *Idee eines ABC der Anschauung* (1802), *Die ästhetische Darstellung der Welt als das Hauptgeschäft der Erziehung* (1804), *Standpunkt der Beurtheilung der Pestalozzischen Unterrichtsmethode* (1804), *Allgemeine Pädagogik* (1806), *Erziehung unter öffentlicher Mitwirkung* (1810), *Über die dunkle Seite der Pädagogik* (1812), *Das Verhältniss der Schule zum Leben* (1818), *Briefe über Anwendung der Psychologie auf die Pädagogik* (1831), *Das Verhältniss des Idealismus zur Pädagogik* (1831), *Umriss pädagogischer Vorlesungen* (1835), *Umriss der allgemeinen Pädagogik* (1841). Of these the most important are the *Allgemeine Pädagogik* and *Umriss pädagogischer Vorlesungen*. The principal works of Herbart are accessible in English translations, under the titles of *The Science of Education*, translated by H. M. and E. Felkin, *Outline of Pedagogical Doctrine*, A. F. Lange and C. De Garmo (New York, 1901), *Herbart's ABC of Sense-Perception and Introductory Works*, W. J. Eckoff (New York, 1896), *Application of Psychology to the Science of Education*, B. C. Mulliney (New York, 1898), *Letters and Lectures on Education*, Felkin. In addition Herbart's *Textbook of Psychology*, translated by M. K. Smith (New York, 1894), should be consulted for an understanding of the ultimate and fundamental principles of his theory, which is based, however, as much upon the results of his own experience as the logical implications of his philosophy and psychology. **HERBART SOCIETY.** — The National Herbart Society for the Scientific Study of Education was organized at the Denver meeting of the N. E. A. in 1895 "to study and investigate and discuss important problems of education. Its members do not subscribe to the doctrine of any one leader, but seek for fair and thorough discussion." Professor De Garmo was the first president, and Professor C. A. McMurry the secretary, the council included President Butler, Chancellor Elmer E. Brown, Professors John Dewey, Frank McMurry, Wilbur S. Jackman, Levi Seeley, and C. C. Van Liew. Yearbooks are published, and discussed at the annual meetings. In 1902 the scope of its interest was broadened, and the society became the National Society for the Scientific Study of Education, which "contemplates a serious, continuous, intensive study of educational problems. It stands for no particular creed or propaganda. In aim and spirit and method it seeks to be scientific." The Yearbooks are published by the University of Chicago Press.

**HERBERT, EDWARD, LORD HERBERT OF CHERBURY (1583-1648).** — One of the most original thinkers of his time. His views on education are to be found in the *Autobiography* and in his *Dialogue between a Tutor and his Pupil*, which was first printed in 1768. On reaching school age, children should have an attendant to take care of their manners as the schoolmaster attends to their learning, and the two tutors should not interfere with each other. After the alphabet is learned, then should be studied the shortest and clearest grammars, e.g. books (such as Comenius's *Janua*), in which Latin and Greek are given in parallel columns. He expresses disapproval of the logic of wrangling, he approves the parts of logic which help to "deduce proofs from firm and undoubted principles, to distinguish between truth and falsehood, and to discover fallacies." The education of most worth consists in the training in goodness and virtue, learning and knowledge, as to which Herbert, like Locke afterwards, regards virtue as much before learning.

In the *Dialogue between a Tutor and his Pupil* the pupil has made himself acquainted with logic, geography, chronology, and history. The tutor enlarges on the usefulness of a knowledge of botany, i.e. especially of herbs, on diagnosis of diseases, on astrology and

astronomy. The tutor holds that amongst sciences, mathematics, divinity, and philosophy are the most important. Mathematics is the most "undoubted and certain" of the sciences.

**HERDER, JOHANN GOTTFRIED (1744-1803)** — One of the most eminent writers of the classical period of German literature; born at Morungen, near Königsberg. Receiving the rudiments of learning from his father, a poor sexton and schoolmaster, he entered the local Latin school, where the mechanical methods of teaching left him in a spirit of revolt which showed itself in his later ideas on education. In 1762 he went to the University of Königsberg, intending to study medicine, which, however, he soon deserted for theology and philosophy. He thus came under the influence of Kant, who led him to study Bacon, Locke, Hume, and Rousseau. To support himself he taught in a local school and showed such ability that he was appointed to the Cathedral School at Riga, where he gained an insight into the problems of education and school administration (1764-1769). On resigning his position he visited the most important educational institutions of France, England, and Germany, and in a diary which he kept he sketched the plan of an ideal school, not unlike the modern *Reformgymnasium* (see GERMANY, EDUCATION), and later realized by him to some extent in the Weimar gymnasium. For a time he acted as private tutor and went with his pupil to the University of Strassburg, where he met Goethe, through whose influence he subsequently obtained the position of chief pastor and superintendent of schools in the Duchy of Weimar (1776-1803).

Herder's influence on German thought and education was profound. Although not himself a creative poet, he brought about an appreciation of native, original poetry in the folk-songs of all races. He laid the foundations of comparative philology and of a comparative science of religion and mythology. In his greatest work, *Ideen zur Philosophie der Geschichte der Menschheit* (*Ideas for a Philosophy of the History of Humanity*) (1784-1791), he developed a magnificent conception of history as a continuous revelation of the divine spirit in humanity. (See Paulsen, *German Education, Past and Present*, p. 158.)

Herder was by nature eminently an educator. His occupation with science and literature was never looked upon by him as an end in itself, but always as a means of influencing other minds, and of social reconstruction through

education. He worked indefatigably for the improvement of the Weimar schools, instituting a seminary for the preparation of rural teachers, raising their salaries, and even writing some elementary textbooks. His chief educational work, however, was in the field of secondary education, and there he is prominent as one of the leaders of the movement known as "Neo-Humanism" (*q.v.*).

The standard edition of Herder's works is that by B. Suphan (Berlin, 1877) in thirty-two volumes. The thirtieth volume contains his pedagogical addresses and articles. Some of the most important of his works, besides those mentioned above, are his work on the *Origin of Language* (1772), his collection of popular poetry, *Stimmen der Völker in Liedern* (*Voices of the Peoples in Songs*, 1778-1779), his translation of the Spanish romances of the *Cid* (1805), and his treatise, *Vom Geiste der hebräischen Poesie* (*Spirit of Hebrew Poetry*, 1782-1783). **HEREDITY** — By heredity is commonly meant those characteristics which the child derives from his ancestors. It is evident, however, that these include many qualities that are transmitted through education. Hence the term has come to be restricted to characteristics that are derived from the original constitution of the germ cell from which the individual is developed. In so far as these qualities are similar to those of the ancestry, they are ascribed to heredity; in so far as they are different, they are denominated variations in heredity.

The extent of hereditary similarity between offspring and ancestry is plainly not revealed until the child has grown to maturity. What, therefore, is inherited is a tendency on the part of the germ cell to grow into the forms and functions of its progenitor. During the expansion of these tendencies they are in the higher species, and especially in man, so modified by environmental influences that it is difficult to determine how much of the adult equipment is derived from either source. (See **ACQUIRED CHARACTERISTICS**.) It is evident that education or circumstances cannot produce either genius or unusual talent; nor is it,

as a rule, responsible for physical or mental deficiencies, although these may result from disease, imperfect nutrition, accident, etc. On the other hand, there can be little doubt that the difference between efficiency and incompetence, or between morality and immorality, is in most cases due in whole or in part to training and to the relative suitability of the conditions of life to the inherited peculiarities of the individual. Thus while education cannot affect those fundamental characteristics on which our rating among our fellows depends, it can develop in most a fairly high degree of efficiency in some specialty. The responsibility of the agencies for education is, therefore, not lightened by the fact that there are hereditary differences which it cannot create nor overcome.

It is more easy to compare the functions of heredity and of education in equipping the individual, than it is to compare the actual amount derived from the two sources. In general, heredity gives us a set of powers which furnish a fairly adequate basis to maintain life in a variety of conditions. It gives capacities. Education, on the other hand, fits us to one or a few specific conditions. Heredity adapts to the permanent, education to the transitory. Heredity gives to each generation a capital of approximately the same amount, leaving to education to invest this fund in the enterprises suggested by the circumstances of the individual. It follows that there is a line of demarcation between heredity and education. Heredity gives such specific qualities as are a permanently useful equipment for the species, together with the capacity to learn others such as will be needed to adapt the individual to the peculiar circumstances of his own life. The acquired characters, on the other hand, are not to any extent inherited, since, constituting as they do adaptations to conditions likely to vary from age to age and from individual to individual, their inheritance would be apt to burden the offspring with many useless, if not positively injurious traits. Thus heredity gives us the power of speech, but education determines the language, the style, etc.

The higher species find life conditions far more varied than do the lower ones. They need, in consequence, greater adaptability, greater capacity to learn. To facilitate learning their heredity consists more largely in imperfect instincts or instinctive acts. These are such as require education in order to be brought to such a form as to function effectively. In man, as Professor James points out, there are more instincts than in any other animal, but they are also more imperfect. Such imperfect instincts, together with the equipment of activities which is instinctively utilized to satisfy them, and the array of other activities that can be utilized to perfect the mechanism by which they may be adequately met, constitute the so-called capacities of the individual. (See **ABILITY**.)

Heredity has been defined as made up of characteristics derived from the original constitution of the germ cell. It should be noted, however, that such simple forms of reproduction as the mere division, or fusion of the parent body, or budding, do not involve specific germ cells. In such cases the offspring is simply part of the body of the parent, separated to assume a form better adapted to the continuance of life and growth. In most respects it resembles the mature organism from whence it sprang. The phenomena of heredity become more complex and striking where there are special reproductive elements, germ cells, which begin life in forms quite distinct from those of the parent, but tend to grow like the latter. The specific nature of those qualities in the germ cell which cause it with growth to assume more and more the form of the adult has been a matter of much speculation and dispute, and to-day the theories on the subject may be regarded as little more than conjectures. The older idea was that of preformation, that is, that a miniature of the adult exists in the germ cell and could be revealed to the eye, if our microscopes were sufficiently powerful. This theory contains the evident truth that the structures of the adult are, at least, implicit in the constitution of the germ cell. On the other hand, we have the theory of epigenesis, according to which the structures of the adult are a result of the development and differentiation of the germ cell. This theory may be said to have been fairly well established by the investigations of Wolff (1759) upon the development of the chick. Granting the truth of the idea of epigenesis, the biologist is still confronted with the difficulty of accounting for the regularity with which a germ cell under normal conditions differentiates into an adult form that is in the main a reproduction of that of the parent. What is there in the germ cell that causes the adult form to be implicit or predetermined in it? According to one view, which will be recognized as akin to the preformationist theory, the multiplication and differentiation of the germ cell is simply the separation of quantitatively distinct units, each of which represents a specific structure in the adult form. These units are supposed to be found in the nucleus of the germ cell. Spencer calls them physiological units, Weismann determinants. The theory more commonly held to-day is that the differentiation of the structures of the adult form is a result of the various tensions set up among the multiplying cells, and that these spring from the physical and chemical or physiological properties of the nucleus. In these properties the whole of the adult organism is implicit, very much as the whole of the geometry is implicit in the definitions, axioms, and postulates with which the geometer starts. They constitute the plan along the lines of which growth must tend to proceed, if it goes on at all.

We have so far considered the problems that arise because of the deposition in a minute and apparently undifferentiated germ cell of all the potentialities later revealed in the growth of the individual. There remains the problem of the source of these hereditary qualities. In this connection we have to consider first the relation of the germ cells to the body cells of the parent, second, the results of the union in the germ cell of a male and a female element, the sperm cell and the ovum, and third, the laws that determine the character of the offspring.

Two theories exist as to the relation of the germ cell to the body cells of the parent. According to one, which is typified in Darwin's notion of pangenesis, all the cells in the body of the adult contribute minute particles which enter into the germ cell. The latter is therefore the creation of the differentiated body cells, a composite of their representatives. According to the other theory, the germ cells are isolated from the body cells, and are not influenced by the history of those. As the germ cell develops, there is a separation between certain cells which remain in a primitive undifferentiated form as germ cells, and body cells which take the forms apparent in the developed adult. Thus the new generation springs from cells similar to those that gave rise to the parent, and not from cells modified by a life history. There is, in the language of Weismann, continuity in the germ plasma, or at least in the germ cells.

The theory of pangenesis is not supported by the existence of any mechanism evident to the anatomist. It is a purely hypothetical explanation to account for the inheritance of acquired characters, *i.e.* such as are the effect of external agencies upon the body cells. Inasmuch as such inheritance is undoubtedly comparatively slight, and is not demonstrably existent at all, it would seem that pangenesis is an improbable explanation of a questionable fact. On the theory of the continuity of the germ cells, the acquired characters would be, for the most part, not inherited. Only such general effects of the environment as could reach the germ cells as well as those of the body, *e.g.* the effects of nutrition, drugs, etc., would be impressed upon the tissue from which the new generation takes its rise.

Reproduction in the higher organisms usually involves the union of the sexual elements, known as amphimixis. On the other hand, with animals as high up in the scale of life as the articulate, parthenogenesis, or the development of the ovum without fertilization, often occurs. Experiments on the sea urchin show that the ovum of this species may be stimulated by chemicals so that it will begin to evolve into an individual. If all reproduction were of this character, the problem of the source of heredity would be simple. On the other hand, amphimixis presents a variety of sources from

which the hereditary characteristics might spring. Among the earlier biologists some maintained that these traits all came from the female, the male element simply stimulating the ovum to develop, others held that all heredity came from the male, the ovum contributing merely nutriment and a favorable environment for development. Both views are now known to be erroneous. The hereditary characters may come from either parent or from both. They may come from grand-parents and include traits that have not appeared in the parents. They may even come from more remote ancestors. Such cases illustrate what is known as reversion. The reappearance of a trait long absent from the stock is called atavism. Degeneration is frequently a result of reversion or atavism. Where nearly all the characters of the offspring are derived from one or the other parent, the inheritance is said to be exclusive. The inheritance of special traits from either parent is called particulate. Particulate is opposed to blended inheritance, where a character in the offspring is a compound of characters derived from both parents. Eye color usually illustrates particulate inheritance. Stature more commonly is a case of blended inheritance.

The great variety of results thus displayed in the phenomena of hereditary transmission suggests the hypothesis of a complicated set of characters in the germ cells representing traits derived from a great number of ancestral sources. Weismann supposed that the process of determining which of these should make up the inheritance of any individual consists of a struggle between germinal units which he called germinal selection. The existence of such selection is not generally accepted by biologists. It is further evident that the formulation of laws of heredity that will enable one to forecast the character of the offspring of any sexual union must be exceedingly difficult. Such laws must cover the phenomena of reversion and atavism, of exclusive, blended, and particulate inheritance, as well as the liability to variation from any hereditary character.

So far only two laws of heredity have been worked out with anything approaching mathematical precision. These are Galton's law of filial regression and Mendel's laws of inheritance in hybrids. Galton's law of filial regression deals with the tendency of the children of unusual parents to approximate more nearly to the common type of the family or stock. Thus the average height of the children of a man and woman both very tall tends, if allowance be made for the difference in stature between the sexes, to be below that of either. This law is an illustration of the tendency toward reversion, and is explained by Galton as a result of the combination of ancestral influences in the heredity of the child. He holds that, in general, the hereditary characteristics are derived as follows: one half from the parents,

one fourth from the grandparents, one eighth from the great-grandparents, etc. It is evident that this rule does not enable any very reliable prediction regarding the qualities of any particular child, but only the average tendency among a lot of children. It explains the fact that children of people of exceptional ability are so frequently mediocre. The same rule should also apply to the children of parents mentally deficient, who should average a better mentality than their parents.

Mendel's laws of inheritance in hybrids enable a much more definite prediction of the character of the offspring than does the law of Galton. It is not known, however, how widely they apply. Where Mendelian heredity exists, the two parents differ in respect to a certain characteristic. Their offspring all resemble one parent in this quality. The trait of this parent is therefore called dominant, while the opposed trait of the other parent is called recessive. In the next generation the recessive trait will appear in one of every four. The descendants of this individual will, if there be no intermixture, possess the recessive trait. It breeds true, or is a pure recessive. Of the other three in this generation of offspring, one, a pure dominant, will breed true to the dominant trait, the other two, which may be called impure dominants, will produce offspring divided as before between dominants and recessives in the proportion of three to one. The recessives will always breed true. One of every three dominants will do likewise, while the other two will be impure dominants, and will have their offspring divided into one fourth pure dominants, one half impure dominants, and one fourth pure recessives. Mendel established and confirmed his laws by experiments on varieties of edible peas. Tall peas, when hybridized with dwarfish ones, give a breed in which the tallness is dominant and the dwarfish quality recessive. Gray mice bred with white mice give a stock in which grayness is dominant and albinism recessive. Mendelian heredity has been shown to exist in maize, rabbits, silkworms, poultry, etc. It has proved useful as a guide in the breeding of desirable types of plants and animals.

Other laws of heredity, such as that inbreeding strengthens the characteristic traits of a stock, whether these be desirable or the opposite, that it is apt to result in reversions, and also in diminishing fertility, size, and vigor, are as compared with Mendel's laws uncertain and not a safe basis for prediction.

As a final point, variations in heredity may be considered. In the offspring traits may appear which vary from any present in the ancestry. Sex undoubtedly may favor this variation. Moreover, it is likely that all living tissue, including the germ cell, has not only the tendency toward continuity or inheritance, but also that toward variation. Variations may be quantitative, "meristic," as variations

in size, proportion of parts, etc.; or qualitative, "substantive," as variations in color, etc. They may be continuous or discontinuous; that is, slight, or so revolutionary as to produce suddenly new types, sports. A variety that is thus varying is called by De Vries a mutating one. He holds that the evolution of species takes place by such extraordinary leaps rather than by slow accumulation of continuous variations under the influence of selection. In this way he avoids the objection urged against Darwin's view, namely, that slight chance variations are inadequate to gain any such advantage in the struggle for existence as to favor the survival of their possessors. His view is that evolution takes place by heterogenesis or mutation, rather than by the natural selection of slight chance variations.

Another way of avoiding this objection to Darwin's theory is to suppose that variations in heredity may not merely be those that occur by chance, and so, if slight, incapable without selection of accumulating into a modification of types, but also that they may in many cases naturally tend toward better adaptation, that is, be orthogenetic.

It is likely that the tendency toward orthogenetic variation may not be inconsiderable, and that it leads on to progress without selective influences. E. N. H.

**HEREDITY, SOCIAL.** — In the reaction from the doctrine of the inheritance of acquired characteristics (*q.v.*), it became evident that culture is not transmitted physically or biologically, but through the perpetuation of social customs and institutions; and that the individual comes to a personal participation in the culture of the race only by means of contact with the abiding social environment. The phrase "social heredity" was coined to express this indirect method of transmitting the achievements and acquisitions of the past.

**HERGENROTHER, JOHANN BAPTIST** (1780–1835) — Bavarian educator and director of a normal school at Würzburg. Born at Bischofsheim of a poor artisan family, his ability attracted the notice of the pastor who prepared him for the University. He entered the University of Würzburg and studied theology. For a time he was curate near Würzburg until in 1818, through his eloquence and ability in imparting religious instruction, he was appointed Director of the normal school at Würzburg, attended by students of all denominations. Although himself a Catholic, he endeared himself to all by his broad-mindedness. His work shows almost entirely the influence of Pestalozzianism, as does also his *Erziehungslehre im Geiste des Christenthums* (*Theory of Education in the Spirit of Christianity*) in which he discusses educational theory, training, and method from the religious standpoint. In 1832 he was removed from his position for political reasons and became pastor at Bamberg.

**HERIOT, GEORGE** (1563–1623) — Founder of the school bearing his name situated in Edinburgh, Scotland. A goldsmith by trade, he was appointed crown jeweler to King James VI of Scotland and I of Great Britain. On his death, he bequeathed the bulk of his fortune for erecting and maintaining a hospital and for the maintenance, relief, upbringing, and educating, as far as the means would allow, of so many poor, fatherless boys, freemen's sons of the city of Edinburgh. The management of the trust funds was placed in the hands of the city magistrates and the city ministers. Steps were taken soon after his death to carry out the testator's wishes, and in 1659 the hospital was opened with thirty boys. At first the boys were merely housed within the hospital buildings, receiving their education at the high school of the city, until they were fitted to proceed either to the university or to enter upon apprenticeship to a trade. Gradually the un-

struction began to be given by the members of the hospital staff, until in 1809 it was resolved that it was no longer necessary for any of the boys to be educated at the high school. From that date until 1886 the hospital existed as a school giving both board and education to a number of fatherless boys. In 1837 the income of the trust was more than sufficient to maintain the hospital school, and it was resolved to open and to maintain a free, elementary day school for the education of the children of the poor. Gradually, as funds were available, additional schools were built, until in 1872 thirteen schools had been established, providing free education for over 3500 children. The Education (Scotland) Act of 1872 transferred the duty of making such provision to the State. In 1886 the boarding system at the hospital was abandoned, and in its place each selected applicant for the benefit of the trust received free education and a maintenance allowance of £20 per annum. The hospital school has now developed into a large secondary school providing an education of a modern type to over 1200 boys, and carrying its pupils to the doors of the universities. The benefits of the trust are now open to girls as well as to boys. In 1886 the governors of the trust took over the management of the Watt Institution and School of Arts, an evening school for the technical instruction of the artisan, and the transferred school is now known as the Heriot-Watt College. This institution has developed into a technical college providing both day and evening instruction for its pupils.

**HEROIC EDUCATION** — The title given to a treatise on gentlemen's education written by a writer who only signs his initials — I. B. — in 1657. I. B. represents that a lady showed him the treatise when it was only a "confused heap, without method or embellishment," but that he recognized that it was "the product of some great and knowing spirit." He therefore edited it and published it with the title: *Heroick Education, Or Choice Maximes and Instructions, for the most sure and facile training up of youth, in the ways of eminent learning and virtues. A Treatise very necessary for all men; but most especially for such as undertake the charge, to govern the young Nobility and Gentry.* By I. B. Gent. F. W.

See GENTRY AND NOBLES, EDUCATION OF.

**HERON**. — One of the great teachers of the Alexandrian School, and the leading engineer of the Greeks. He was formerly thought to have lived in the first century B. C., but later

investigations have led to the belief that he flourished in the first century of the Christian era. He was interested chiefly in mensuration, and his formula for the area of a triangle in terms of its sides still appears in elementary textbooks. This formula is  $A = \sqrt{s(s-a)(s-b)(s-c)}$ , in which the sides are  $a$ ,  $b$ , and  $c$ , and the semiperimeter is  $s$ . Such a formula would not have been allowed by Euclid and his school, because it involves the product of four lines and could not therefore have represented a solid in three dimensions or a rectangle in two. In physics Heron showed great ingenuity, and he describes a large number of toys or models, some of which have since been utilized in a practical way. These include a steam engine and a force pump. He introduced into the schools more successfully than any of his predecessors the idea of applied mathematics, and it is possible that this may have had its influence in hastening the temporary decline of pure mathematics, even as a similar movement in America to-day may bring about such a result. It is more probable, however, that his attitude was that of the general spirit of the time, and that the hibernation of pure science was independent of his efforts. D. E. S.

**HERRAD** — Abbess of Odilienberg or Hohenburg (1167–1195), born of a noble family in Alsace. It is recorded of her that she promoted studies in the nunnery, and to this end wrote the *Hortus Deliciarum* (*Garden of Delights*), which, having found its way to the library at Strassburg, was there burnt in 1870. Extracts and copies of the illuminations which were in all probability the work of the abbess herself remain. The *Hortus Deliciarum* contained extracts from the Bible, church histories, church Fathers, philosophy, astronomy, geography, nature study, liberal arts, chronology, and poems and hymns to be sung by the nuns. The work was intended for the education of the novices. A few excerpts from pagan writings were also included. The illuminations cover a multitude of subjects to illustrate the text.

**HESSUS, HELIUS EOBANUS** (1488–1540). — A German humanist, who was admitted to be

the best Latin poet of his time. He studied at the University of Erfurt, and became rector of the school of St. Severus. From 1517 to 1526 he was Professor of Poetry and Eloquence at the university, and was an important figure in the literary coterie at Erfurt. With Ulrich von Hutten he joined in the national movement which was associated with the Reformation, although he seemed to fear that the humanistic tendencies were being pushed on one side. For a short time, 1526-1533, he was rector of a school at Nuremberg. On his return to Erfurt he found that the university had practically ceased to exist before the rapid rise of Wittenberg. In 1536 he accepted a call to Marburg. Hesus was a prolific writer, and showed equal facility in all branches of verse. He translated the *Psalms*, *Ecclesiastes*, Theocritus' *Idylls* and Homer's *Iliad* into Latin, and in imitation of Ovid he wrote *Herodes*, or letters from holy women. He published collections of his writings as follows: *Operum Helii Eobani Hessi Farragines duæ*, and *Silvarum Libri IX* (containing the poetical description of Nuremberg, *Urbs Noriberger illustrata Carmine heroico*). Although recognized as a leader, Hesus never exercised much influence on contemporary movements. His life and letters were issued by his friend Camerarius in 1553.

**HEURISTIC METHOD** — The inductive method of modern science when applied to the teaching of children is called the heuristic method. The term is current in English pedagogy, "inductive method" being more frequently used among American teachers. The command, "never tell a child anything that he can find out for himself," expresses the essential attitude of those who believe in the heuristic or inductive method. It aims to place the learner in the position of a discoverer of truth, so that facts and generalizations will emerge in proper order and relation in the child's mind. Its extreme application implies that each child will experiment and observe for himself, thus the teaching of physics and chemistry may be conducted by means of individual experimentation in the laboratory, demonstration by the instructor being completely eliminated. In its pure form the heuristic method is seldom used. A modified inductive method that avoids dogmatic teaching without incurring the waste of an extreme heuristic mode of procedure is current among all progressive teachers in the elementary schools, taking such names as "inductive teaching," "developmental instruction," "laboratory method," and "indirect method."

Such modifications of an extreme heuristic mode of teaching recognize two important pedagogical facts. (1) That the child learns best through his own activities, and (2) that the pupil may understand many facts without going through all of the detailed efforts and failures that have accompanied their original discovery. H. S.

**HEYNE, CHRISTIAN GOTTLÖB** (1729-1812). — One of the foremost classical scholars in Germany at the close of the eighteenth century, and a leader in the new humanistic movement of the period. The son of a poor weaver, Heyne underwent the greatest hardships to secure an education at school and at the University of Leipzig, where he came under the influence of Ernesti (*qv*) and Johann Friedrich Christ. For a time he managed to secure a livelihood as assistant librarian, and then as tutor, until in 1763. Though only known for editions of Tibullus and Epictetus, he was invited to succeed Gesner (*qv*) as Professor of Eloquence at the University of Göttingen. In this position he transformed the dry, formalistic study of the classics into a living, vital force, aiming at a true appreciation of the works of antiquity through a knowledge of history, antiquities, and archaeology. Regarding the classics as the only method of approach to the good, the true, and the beautiful, Heyne wished in that way to influence the culture of his time. His influence was widespread, and from his philological seminar, the entrance requirements to which were rigorous and in which the students received government grants, there came many future university and school teachers, imbued with a new attitude towards the classics. But Heyne also had direct contact with the schools, as inspector of the school at Ilfeld he drew up new regulations in 1770 which reorganized the curriculum on a basis of Greek, and in

1798 he performed a similar work for the gymnasium at Göttingen. Besides his editions of Tibullus and Epictetus, Heyne published editions of Vergil, Pliny, Apollodorus, Pindar, Conon, and Parthenius and Homer's *Iliad*; in addition he wrote treatises and essays on a great variety of subjects collected in six volumes as *Opuscula Academica*, and numerous reviews in the Göttingen *Gelehrte Anzeigen*, of which he was the first editor.

He was instructor in academies at Woodstock, Vt., and Emmitsburg, Md., and was later professor in Heidelberg College and the Theological Seminary at Mercersburg, Pa. He was state superintendent of public instruction in Pennsylvania from 1881 to 1889, during which time he was also editor of the *Pennsylvania School Journal*. He was the author of numerous educational essays. W. S. M.

**Reference:—**

- MCCARKY, J. P., ed. *Dr. Higbee Memorial Volume*. (Lancaster, Pa., 1890).

**HIGH SCHOOL.**—The term "high" as applied to a school, which in these modern days in England has become almost synonymous with a high-class secondary school for girls and in America with a public secondary school, is one really of very great antiquity, as applied to a "public" school or grammar school. Originally of course high schools were exclusively for boys and youths, or young men, for females were not so much rigidly excluded as not contemplated by any one as admissible or seeking admission to the "general" or "public" grammar school. The term "high" was in common

use in English for chief or principal, as in the word "High Street," which had no relation to steepness, or the Lord High Chancellor of England, *Summus cancellarius Anglie*, as distinguished from the Chancellor of the Exchequer, the King's chancellor, and not the chancellor of bishops or other inferior magnates. It was rendered in Latin indifferently by the words *summus* or *altus*, and possibly *generalis* and *magnus*. In connection with a school one of the earliest uses of it in England is an inquiry held at Winchester in October, 1373, in a suit between William of Wykeham, Bishop of Winchester, against the Master of the Hospital of St. Cross near the city for malversation of the revenues of the hospital. It was then given in evidence that among the hundred poor, who according to the foundation and ancient custom were every day entertained at dinner in the "Hundredmennehall" of the hospital were 13 poor scholars of the grammar school, sent by the master of the High Grammar School of the city (*magistrum summe scole grammatice civitatis Wyntonie*). The witnesses take this custom back in their own knowledge to 1313, and if it did not date to the actual foundation in 1130, it was at least not later than the secondary foundation or augmentation of the hospital in 1200. In a "Tarrage" or assessment of land in the city of Winchester, for the maintenance of its walls in the early part of the reign of Richard II, c. 1377, appears the item "From the High School" (*De alta scola*), 12d. and on the back is written "From the master of the High School" (*De magistro alte scole*), followed by a blank, apparently showing that he had not yet paid, and "From Sir John of the same place 6d." The Sir means that John was a priest and probably usher of the school, who paid half its assessment. This school was the old city grammar school which was the subject of a lawsuit reported in John of Salisbury's letters about 1155, and no doubt the same as that to which Alfred the Great is said, in Asser's *Life* of him to have sent, c. 893, his younger Ethelward to learn Latin. This school continued after the foundation of the rival grammar school of Winchester College in 1382. For in January, 1407, we find in the Hall book of the college that the master teacher of the High School was at supper at the high table (*Magister Informator alte scole ad cenam in alta mensa*), i. e. having supper with the Warden and Fellows. In 1488 we find the Bishop's official granting license to one Furnew to "teach and inform in grammar and literature in the school of Winchester, called in the vulgar tongue 'The High Schole,' and forbidding any one else to teach school in Winchester, the master and scholars of the Blessed Mary's College, founded by the Lord Wykeham, only excepted."

The ancient cathedral or city grammar school at Exeter was also called the High School. The High Master of the city school (*summus magistrum scole civitatis*) was empowered by the

statutes of Bishop Grandison on Nov. 18, 1332, completing the intended foundation of his predecessor Bishop Stapledon, the founder of Stapledon Hall, now Exeter College, at Oxford, to elect the twelve boys who were to be lodged and boarded in St. John's Hospital there under a tutor and to attend the city grammar school. In 1345 a new school and house for the master was built by Dean Richard de Braylegh. There is no specific evidence that it was called the high school until an entry in the Act Book of the chapter on Jan. 22, 1530, when the secundanes, clerks of the cathedral who served various altars while in training for the priesthood, had 6d a quarter deducted from their salaries "for the stipend of the master of the High School (*altarum scholarum*) for teaching them." From then until the year 1759, when the school came to an end, and especially after the year 1632, when the endowed Free Grammar School, which finally killed it, was established, it was also generally called the High School, the new school being called the Grammar School, or the Free School. This Free Grammar School was established by the city in opposition to the dean and chapter and the bishop, chiefly because the old High School charged tuition fees in the hall of the church of the dissolved St. John's Hospital, under a patent obtained from Charles I in 1632. But as late as 1662 a medical doctor, Robert Vilvaia, who established four exhibitions for Exeter boys at Exeter College, Oxford, directed that two of them should be given to boys from "the High School," and two out of the Free Grammar School. The last master of the High School was appointed in 1739, and on his death it ceased.

At Lincoln in 1388 we find the cathedral or city Grammar School, called the High School (*magnarum scholarum*), in an appointment of an usher or second master, in contradistinction to a new grammar school really established for the choristers, and in 1406 its superiority was recognized by the boys in the latter being obliged once a term to go down to the High School (*scolas generales*) and sit in it under the teaching and chastisement of its master.

In the nineteenth century there seems to have been a tendency to revive the title of high school, especially in Scotland, where the Edinburgh High School, a title appearing in town records of 1534, was accepted as the model. Thus the Glasgow Grammar School became the High School in 1834; the Sterling Grammar School became the High School in 1856; at Dundee an academy, grammar and another school were amalgamated into a high school in 1859. In England the title of the Nottingham Grammar School (f. 1513) was changed to High School in 1868, and in 1878 the Oxford High School for boys was founded.

In France the distinction was made between the High School, meaning the city or cathedral grammar school, and the lower schools in various parishes, the teaching in which was not

allowed to go beyond the parts of speech. Thus in 1324 and 1325 the rector of the schools of St. John-en-Vallée and the schoolmaster of St. Andrew's Chartres were inhibited from teaching beyond the *Donat* (Donatus' *ars minor*), except in the High School (*scolis magnarum Carnetensibus*), and in 1358 a master is admitted not as usual primarily to "the School of Chartres" but as master of the High School (*magnarum scholarum*). So at Paris in 1380 there were some twenty-one *petites écoles* under the Precentor of Notre Dame giving elementary instruction, as contrasted with the High School, the *grande école*, the Grammar School under the chancellor.

In Germany the term high school, *Hochschule* or *Hohe Schule*, was taken up at the period of the Renaissance to designate emphatically the enlarged schools with their wider humanistic curriculum, which became almost universities, alike in number of students and in subjects, and were solely or largely under the management of the town authorities instead of that of the Church. At Vienna we hear of Johann Spieshammer at the end of the fifteenth century at the age of eighteen lecturing at the High School on Lucian, Sallust, and Cicero. The proposal for a High School at Strassburg in 1501 was intended to restrict itself to classics. The High School at Nuremberg was established by Melancthon (*qv*) in 1526. The term received a sort of consecration from the famous school established by Sturm at Strassburg in 1536. From that time the term vied with *gymnasium* and the usual name for the highest form of classical school, the public school of England. (See HIGHER EDUCATION.)

It is not quite clear how the term came to be used in America for the same thing, when it had died or was dying out in England in the seventeenth century. It appears to be definitely established that the term was borrowed directly from the Edinburgh High School, where at the beginning of the last century Professor Pillans (*qv*) was experimenting with the monitorial system. At Boston the English Classical School became the English High School in 1824. The change may have been influenced by an article in the *North American Review* written by John Griscom (*qv*) on the work of the Edinburgh High School. Griscom also established a High School for Boys in New York, which was opened in 1825, although it was under consideration for one or two years before that date. The use of the term High School in Pennsylvania in colonial times does not seem to have any influence on its subsequent history. (See Brown, E. E., *Making of our Middle Schools*, pp. 303 ff., New York, 1905.) That it became acclimatized is certain, and it is quite certain that it was to the American use of the term that its revival in England was due when the new movement for the higher education of girls in schools similar to those of boys of the same class began in 1848 with the

Camden High School for girls, from whence it has been adapted all over England as the generic term for a girls' Public School. A F L

**HIGH SCHOOLS IN THE UNITED STATES. — History** — The first high school in the United States was established in Boston in May, 1821, as the Boys' Classical School, complementary to the Boys' Latin Grammar School. The term "high school" was not officially applied until 1824, and was not employed in the Massachusetts statutes until 1840. Meanwhile in 1826 a high school for girls was established in Boston. This school existed only for two years, not because of unpopularity, but the reverse. So large was the attendance that one school would not accommodate the applicants, and the upper grades of the common schools were expanded to meet the needs of the girls. The report of the committee in 1821 clearly indicates the situation which soon called for the establishment of this type of school all over the country —

"The mode of education now adopted, and the branches of knowledge that are taught at our English grammar schools are not sufficiently extensive nor otherwise calculated to bring the powers of the mind into operation nor to qualify a youth to fill usefully and respectably many of the stations, both public and private, in which he may be placed. A parent who wishes to give a child an education that shall fit him for active life, and shall serve as a foundation for eminence in his profession, whether men, artile or mechanical, is under the necessity of giving him a different education from any which our public schools can now furnish. Hence, many children are separated from their parents and sent to private academies in this vicinity, to acquire that instruction which cannot be obtained at the public seminaries."

The Latin grammar school was essentially a college preparatory school, and its curriculum was not suited to the common needs of life. The academy offered a curriculum of practical studies, but it was a private institution requiring considerable tuition fees, and it was, therefore, somewhat exclusive. A school was needed to provide three or four years of training beyond that given in the elementary schools, that should have a practical curriculum like that of the academy, and that should be free, like the Latin grammar school. (See GRAMMAR SCHOOL, ACADEMY) Previous to the founding of the Boys' Classical School, twenty-six academies had been incorporated in Massachusetts.

In 1827 the first state high school law was passed, again in Massachusetts. This required such a school in every town of over 500 families. However, for many years the academy (*qv*) still continued to be the dominant secondary school, even in Massachusetts. In 1840 there were 114 incorporated academies in the state, and only 18 high schools, though strict compliance with the law of 1827 would have given 44. From this time on the number of high schools increased very rapidly. By 1861 the State Board of Education claimed that there were 102 high schools in the state, teaching Latin and Greek. There were no doubt at least one hundred well entitled to this claim, though recent official attempts to

summarize the high school development in the United States credited no more than that number to the entire country, and only eleven to Massachusetts. By 1862 the system was well established in Massachusetts, although less than 70 per cent of the towns of the state met the legal requirement, even allowing the 102 schools claimed by the state board.

Meanwhile, the development of the high school had gone on elsewhere, though more tardily. In New York the conflict between the high school and the academy resulted even more favorably for the academy than in Massachusetts. While Governor Clinton during the decade 1817–1827 advocated the establishment of high schools in every county, under the monitorial system, and connected with the professional training of teachers, but few of these were founded. The friends of the academy were able to divert the appropriation of state funds to these institutions instead of to the high schools or the normal schools. The "Union Free Schools" Acts of 1853 and 1864 developed many high schools under local control out of the graded free school system.

After the Civil War period the number of high schools increased very rapidly. In 1880, according to the *Report of the United States Commissioner of Education*, there were 800, in 1890, 2526, in 1900, 6005, and in 1910, 10,213. In a little less than one third of these schools there are not more than three teachers; in more than one third, not more than six teachers, in about two thirds, not more than ten teachers. In some of the largest city schools there are as many as 125 teachers and 3000 pupils. The recognized standard high school course is now four years in length, but many schools have a one, two, or three years' course. (See the articles on the separate state systems for the development of their high schools.)

**State Systems** — The high school of the United States has, upon the whole, evolved from the free elementary school. Its development has followed that of its progenitor by approximately a quarter of a century, so that in many states it remains as yet almost entirely unsystematized, so far as the legal aspect is concerned. In a number of states, only the most general legal provision is made for the establishment and maintenance of such schools, while in a few of the Southern and in at least one of the Northern States, New Jersey, no special legal provision is made for them, such schools as exist being considered merely as the higher grades of the public schools. Most of the states have, however, made definite legal provision for these schools, and a large number, such as Maine, Massachusetts, New York, Indiana, Wisconsin, Minnesota, and California, have evolved comprehensive independent laws governing the establishment, maintenance, and management of such schools. But the legal provisions even of these states

differ widely among themselves, so that the laws governing this institution in the United States range from indefinite and badly defined codes in certain states to clear and specific legislation in others.

Nevertheless the high schools in the various states have a remarkable resemblance in external and internal management and control, as well as in their curricula. In general no greater differences exist internally between the high schools of Maine and those of California than may be found to exist between the different high schools of any given commonwealth. This similarity is due to a number of factors in American life and American educational practices. In the first place, the elementary schools, the feeders of the high schools, resemble one another even more closely than do the high schools. The colleges, the universities, and particularly the state universities, the institutions that largely receive the output of the high schools, also closely resemble one another.

The explanation of this close resemblance of the various types of schools in the American system of education is largely due to imitation brought about by the following facts and conditions: (1) most of the states of the Union are relatively new and their populations have been largely recruited from the other older states, (2) the Americans are a migrating people, and recognize no state boundaries in their shifting from place to place, (3) there is wide communication through travel, books, and periodicals, (4) national and state conventions of teachers, principals, and superintendents are held annually, — the state conventions usually employing outside instructors to present the work, (5) teachers are to a considerable extent recruited from the country at large rather than from the local community and state alone, (6) students frequently leave their own communities and state to prepare for their work of teaching. In addition the laws governing the establishment, maintenance, and support of all of these types of schools have been more or less influenced by the laws and practices of other states.

In no point, however, do the high schools of the Union so closely resemble each other as in their curricula. This is due to the fact that this institution has been, and is to-day, fundamentally a preparatory school to the colleges and universities, which by association and concerted action have set a more or less definite standard of requirement for entrance, and thus to a large degree have dictated a common curriculum for these schools. (See COLLEGE REQUIREMENTS FOR ADMISSION.)

Ever since the rise of the high school in this country its ablest advocates have dreamed of it as the finishing college of the common people; but as yet the fruition of this dream has not been accomplished, — unless, indeed,

the college preparatory course can be considered the best preparation for social efficiency. This condition has been no more the fault of the college and the university than of those who have insisted upon a different curriculum, but who in the past have been unable to evolve one definite enough to be workable in any of the thousands of high schools of the country. However, the present widespread interest in vocational, industrial, technical, commercial, and economic training, and the growing interest in the refinement of the other common aspects of life, together with the practical experiments now going on, give a renewed promise for the future of this dream of a people's college. The American high school, then, in so far as it is efficient, owes this efficiency in large measure to the college and the university.

The systematizing of any series of schools of a given type means their unification, and this can be secured only through the operation of one or more of the four following instrumentalities: similar laws governing their establishment, maintenance, and support, like curricula, supervision and inspection, and teachers with similar ideals and training. The first of these will be discussed later.

*Inspection.* — With a few notable exceptions, the only state-wide supervision and inspection that American high schools have received in the past has been upon the motion and at the expense of the state universities, sometimes with, and sometimes without, legal warrant from the state. This inspection, to be sure, has been solely in their own interests, but it has nevertheless tended to systematize these schools not only within the state, but likewise within the country at large. (See ACCREDITED SCHOOLS; ACCREDITED TEACHERS.) As stated elsewhere, these same universities have also unified the curricula of these schools, and through their instrumentality as preparatory schools for high school teachers they have instilled into them similar ideals and have provided them, largely through imitation, with similar methods of procedure in instruction. A few states, however, such as Massachusetts, New York, New Jersey, Wisconsin, and Minnesota, provide in other ways for supervision and inspection. In both Wisconsin and Minnesota the responsibility for high school inspection rests only partly with the state university authorities. In New York, New Jersey, and Massachusetts it is independently conducted. It is worthy of note that all of these states mentioned above give direct financial aid to the least wealthy high school districts. State supervision or inspection, legal requirements governing curricula, and qualifications of teachers, all inevitably follow state financial aid to high schools.

*Organization of Control.* — The most prevalent local political unit of organization for the establishment, maintenance, control, and

support of high schools in the United States is the district, which includes the city or parts of the city, the town or small city, the village, the rural district, or a union of such districts. This system prevails in all of the states in so far as it applies to the cities and larger towns, and in some states it is the only unit of organization for the establishment of such schools. In most instances the local board of school directors or school trustees, which also has charge of the local lower schools, controls these schools. (See CITY SCHOOL ADMINISTRATION.)

In the rural districts of many of the Eastern and Middle Western states the township unit of organization prevails both for elementary and for high school purposes. In certain of these states the district unit of organization prevails for elementary school purposes, while the township unit prevails for high school purposes. In most of them there are also union or joint township high schools in existence. The boards of education which are in control of these schools are elected by the people of the territorial districts maintaining them. In some of the Southern, Western, Rocky Mountain, and Pacific Coast states many county high schools exist, and in at least a few cases joint county high schools. These schools are always under the control either of the county boards of education, which have other duties relating to the elementary schools, or of special county or joint county high school boards. In a few states these boards are appointed by the county courts, in others by the county commissioners or supervisors, and in the remainder of the cases they are elected by the people.

#### E R S

**Rural High Schools.** — Since in general the towns and villages of the United States with populations to exceed 2500 are able to maintain reputable high schools, and since they have for years been doing so, the main problem of rural secondary education has to do mostly with that part of the population residing in the smaller villages and on the farms of the country. The units of organization for rural high school purposes vary widely in the different sections of the country as well as in some of the states themselves, the smallest of these units being the district. These district high schools, in so far as they may be classed as rural, have largely grown out of the elementary schools through the gradual addition of high school subjects and high school grades. This is particularly true in such states as have had the district unit of organization and control in matters of education. In every state where the unit of control is such, and where the law has failed to define the public school as a strictly elementary school, rural high schools have grown up as district schools. The union of districts for high school purposes is also an outgrowth of the gradual extension

of the elementary school. As a type it is the result of combining two or more advanced district schools that had already developed considerable high school work in connection with their elementary courses. The township unit of organization is more prevalent than the district unit, in so far as the term applies to such rural high schools as have state recognition as such. This is a perfectly natural condition, since in most of the older and wealthier states, the Eastern and Middle Western groups, the township constitutes the unit of taxation and organization for public school as well as other civil purposes. The method of uniting townships into high school districts has also been employed to a considerable extent, particularly where the townships covered a small area, or where their most thickly populated areas were adjacent. The county plan of organization is quite largely practiced in the Western and in certain of the Southern states. This plan of organization almost always implies large local support, and is especially adaptable to thinly populated districts. Village and town districts sometimes unite with their counties or with their own townships or with a group of adjacent townships in the establishment and maintenance of union high schools. In fact, in a large number of the states any combination of territory may organize itself into a high school district.

**Curriculum.** — The courses of study in the rural high schools are very similar to those of the city high schools in the states wherein they are located. The most notable difference is that they offer a smaller number of courses, which is a direct result of the small teaching force employed and of the small number of pupils in attendance. Most of the states, recognizing that these schools are at least in theory finishing institutions, have required one course of instruction other than the classical, making the foreign languages elective, if offered at all. In most cases, however, these schools give also a college preparatory course, including at least one foreign language, usually Latin, though the modern languages are rapidly gaining ground.

The present tendency is to create for these schools courses of a more practical nature. This is to be accomplished by modifying the courses and instruction in the sciences, by adding courses in agriculture, stock-raising, dairying, horticulture, and other practical subjects, as demanded by the particular school. So far little of a practical nature has been accomplished in this line. In fact, in regard to practical education, the cities are at the present time far in advance of the rural districts. Some of the Middle Western states, such as Wisconsin, Michigan, and Nebraska, have made considerable progress in this line.

Another tendency worthy of note is that of recognizing and aiding rural high schools

which offer only a partial course of study, particularly the two-year rural and small village high school. Such schools are becoming common in the upper Mississippi Valley, though as yet only a few states have granted them any special financial encouragement. California, with its two-year "Grammar-High" schools (*q v*), is a notable exception in this particular. (See also HIGH SCHOOLS, SUPPORT OF.)

*Statistical Summary* — A statistical statement of the number and condition of the strictly rural high schools in this country is not possible, because, as pointed out above, the statistics of rural high schools proper are combined with those of all villages and towns having populations that do not exceed 8000 inhabitants. The increase in the number of reputable non-urban high schools is a good index to the vitality of the institution at the present time.

The following statistical summary is based on an extended study of twenty states selected because of their availability for the purpose. These were Maine, Massachusetts, New Jersey, California, Colorado, Washington, Connecticut, Vermont, New Hampshire, Michigan, Wisconsin, Minnesota, Ohio, Indiana, Illinois, Iowa, Missouri, Texas, Kansas, and Nebraska. The high school and other necessary statistics for these states for the nine years ending 1906 were compiled, and interpreted with the following general results. —

(1) The average increase in the number of rural<sup>1</sup> high schools in the twenty states was, for the nine-year period, 50 per cent. (2) The average relative<sup>2</sup> increase in the enrollment of pupils in the urban<sup>3</sup> high schools of the twenty states was, for the nine years, 46 per cent, while for the non-urban<sup>1</sup> high schools it was, for the same period, 65 per cent. (3) The average increase to the school in the number of teachers employed in non-urban high schools was, for the nine years, more than 19 per cent. (4) The average decrease in the relative number of one-teacher high schools was, for the nine years, more than 11 per cent. (5) The average decrease to the school in the relative number of two-teacher high schools was, for the nine years, more than 33 per cent.

The general methods employed by different states in extending financial aid to rural secondary education are varied, and are discussed in the section on SUPPORT OF HIGH SCHOOLS.

The influence of this aid upon the rural high schools of these states is clearly shown by the following comparison of the average development of rural secondary education during a period of nine years, 1897-1906, in six states, Minnesota, California, Massa-

chusetts, Washington, Wisconsin, and Maine, — all of which provided state subsidies to rural high schools and two of which also provided for the reimbursement of tuitions, — with the average development of rural secondary education during the same period in eleven states, Nebraska, Ohio, Indiana, Kansas, Colorado, Michigan, Illinois, New Jersey, Iowa, Missouri, and Texas, none of which provided direct state aid to secondary education in any manner whatever. The results were as follows: —

(1) The average increase in the number of non-urban high schools was, for the six states, 68 per cent, for the eleven states, 48 per cent. (2) The average increase in the number of teachers employed to the school in non-urban districts was, for the six states, 38 per cent, reckoned on an average status of 2.4 teachers to the school in 1897; for the eleven states 6.5 per cent, reckoned upon an average status of 2.5 teachers to the school in 1897. (3) During these nine years the average relative proportion (.25) of one-teacher high schools in the six states was reduced 63 per cent, in the eleven states the average relative proportion (.27) was increased 15 per cent. (4) During the same period the average relative proportion (.52) of two-teacher high schools in the six states was reduced 53 per cent, while in the eleven states the average relative proportion (.44) was increased 2 per cent. (5) The average status of enrollment of pupils in all types of secondary schools, 4.44 individuals to each 100 of census (5-18), in the six states in 1897 was increased during the nine years 57 per cent, while in the eleven states the average status of enrollment, 3.68 individuals to each 100 of census (5-18), was increased but 39 per cent. (6) The average status of enrollment of pupils in city high schools, 4.81 individuals to each 100 of census (5-18), in the six states in 1897, was increased during the nine years 52 per cent, while in the eleven states the average status of enrollment, 4.13 individuals to each one hundred of census (5-18), was increased 49 per cent. (7) The average status of enrollment of pupils in non-urban high schools, 2.85 individuals to each 100 of census (5-18), in the six states in 1897 was increased during the nine years 100 per cent, while in the eleven states the average status of enrollment, 2.49 individuals to each 100 of census (5-18), was increased 49 per cent.

Thus it appears that the rapidly developing standard of rural secondary education in the states that provide special financial aid is slowly approaching the increasing standard of the same in the cities of these states. On the other hand, it appears that the rapidly increasing standard of rural secondary education in the states that offer no special aid is slowly diverging from the constantly increasing standard of the same in the cities of these states. On the

# HIGH SCHOOLS IN UNITED STATES

whole the general increase of standard of urban as well as non-urban secondary education has been very rapid in recent years E R S.

**The Curriculum.** — When the American high school first arose, and during what may well be termed the period of its struggle for existence, the need of higher education for any large percentage of our people was relatively slight. With an elementary school system of very meager proportions still in its infancy; with the principle of general taxation for education scarcely established; with little surplus national wealth; with few of the pressing problems of government, industry, and human relations, with which we of to-day are so familiar, not as yet markedly in evidence; and with but a small portion of our present organized knowledge as yet available for purposes of instruction, it can readily be understood that the high school of the earlier period was very limited in its scope, and was demanded by but a very small percentage of the people. Latin, Greek, and mathematics constituted the backbone and the bulk of all instruction; the course of study was the same for all; and the school was useful chiefly as a preparation for entering some one of the denominational colleges of the time.

The past fifty years, however, have witnessed very great and very significant changes in every feature of our national life, and the public secondary school has shared in these changes. Everywhere such schools have been adopted as a necessary part of a system of popular education, new classes of people have been attracted to them, and new subjects of instruction have been provided. The development of the secondary school since 1890, and particularly since 1900, has been marked. With the gradual evolution of the new conceptions as to the purpose and function of public education, there has been a gradually increasing demand that the secondary schools shall more thoroughly meet the needs of the new classes in the population which have turned to them for help and enlightenment. This has greatly changed the nature of high school work.

First to be introduced was history and English literature, and then the modern languages. In the seventies and eighties came the sciences, first in book form and shortly afterward as laboratory studies. Manual training and domestic arts came to be recognized as teaching subjects for special schools in the late eighties, and have since been incorporated as parts of regular high school instruction. Business training, at first introduced as a concession to public opinion and to meet the competition of the private "business colleges," has since been adopted as a useful addition, and, in the larger city high schools, is being transformed into good, strong, commercial or business courses (See COMMERCIAL EDUCATION.) Still more recently agriculture has been admitted as a useful subject of instruction, and the develop-

# HIGH SCHOOLS IN UNITED STATES

ment of the agricultural high school has been very rapid (See AGRICULTURAL EDUCATION.)

These many additions have affected the high school curriculum in two ways: (1) the old course has been expanded and crowded, resulting in the introduction both of elective studies and elective courses, and (2) new types of high schools have arisen by the side of the old to minister to the new needs. These changes may be illustrated by a few typical examples of high school curricula, chosen from different types of American high schools, and by an enumeration of the different types of high schools which have been formed.

*Types of High School Curricula* — I A small New England high school, in which the one fixed, traditional course of study, almost entirely based on book work, has had to give way to changing demands and admit a few electives during the last two years. This type of school is still very common in conservative communities and among rural high schools.

II A medium-sized city high school, located in the Mississippi Valley. Here, by combinations, five different courses of instruction have been arranged, supposedly to fit different types of individuals. Such combinations are quite common, though the tendency is to decrease the number of required subjects and to increase the number of electives in each. In the administration of the school this is usually done in individual cases, though not indicated in the paper courses of study.

## Rule governing combinations and graduation

(1) Students, to graduate, must complete 15 years' work, viz., four studies each year for three years, and three studies one year.  
(2) Students may, on permission, take as many as five studies or as few as three studies each half-year.  
(3) Students, to graduate, must have had two years' work in groups I and II, one year's work in each of the other groups, and four years' work in some one group.  
(4) Study cards must be made out each half-year, and must be approved by the principal and the parent.

The three types of high school courses given above illustrate the development which has taken place, and the tendency. Excepting agriculture, all new forms of instruction are represented in the one school. The advantages to the pupil are evident, while it is clear that

such grouping of courses to meet individual needs as is provided for in the third type has advantages over that provided in the second type.

In some cities high school development has taken a different direction, and instead of expanding the high school to meet the many different needs, new types of high schools have been founded, and type or class high schools have resulted. There are to-day, in different places, the following different types of secondary schools.

(1) The so-called cultural or general high school; offering courses in the languages, literature, history, mathematics, and some science. This is distinctively a college preparatory high school. (2) The manual training (*q.v.*) high school; offering courses in science, mathematics, modern languages and history, English, and shopwork. This is preparatory for the engineering colleges, and work in shops and trades. It often includes the third type, for girls. (3) The household arts (*q.v.*) school. While usually included under the manual training school, a few such are being established separately. It offers courses in English, history, the sciences, and subjects relating to household management, and is a technical school for women's work. (4) The commercial high school. (See COMMERCIAL EDUCATION.) This is an intensification of the commercial course, and offers good courses in modern languages, history, science, and office practice. It is preparatory for commercial pursuits, on a larger scale than the old business course. (5) The agricultural high school. (See AGRICULTURAL EDUCATION.) This offers courses in English, mathematics, sciences, some manual training and household science, and agricultural studies. It is preparatory for farm life, or for the colleges of agriculture.

It is desirable both that these different types of high schools should exist separately in some cases, and in many other cases should be combined in one. In their beginnings all new types of schools usually prosper better if provided for separately; but, after these new schools have established themselves and their work has been accepted as a good and legitimate educational effort, it is wise then to combine a number of such types in one school, and thus offer a larger range of choice to each high school pupil. The American high school, if it is to realize its highest educational purpose, should be preeminently a place for the testing of capacity, the development of tastes, and the opening up of vocational opportunities of many kinds. This involves intelligent oversight and direction on the part of teachers and principals, a rich and varied curriculum from which to select, and freedom from hard and fast prescriptions.

E P C

### The Elective System of Secondary Schools

— In the course of its evolution, the high school has developed an extensive program of studies, — four or five foreign languages; English for every grade; mathematics for three or more years; two, three, or four sciences, history for two or more grades, and, in addition, manual and commercial subjects. These have contributed to the making of a program far too extensive to be within the reach of any one pupil. For a time with the introduction of new subjects, less and less time was assigned to each, with the result that when the *Report of the Committee of Ten* (*qv*) was written, many large high schools were giving twelve and fourteen weeks' courses in science, short courses in history, and smatterings of three or more foreign tongues. The *Report of the Committee of Ten* greatly emphasized the desirability of an intensive treatment in the high school of relatively few subjects. The effect of this *Report* was only rarely the complete elimination of any subject from the high school, but generally resulted in a tendency to intensify and extend the treatment of each one. More than ever did it become necessary that the individual student should take but a part, and frequently a small part, of the entire range of subjects open to him. Another tendency contributing to the flexible course of study was the increasing range of capacity and interest found in the students of the high school. A variety of studies in science, drawing, commercial branches, and manual training were introduced to meet these demands. A third element in the development of the flexible course grew out of the conception in the *Report of the Committee of Ten* that it was of less importance what particular studies were pursued than what was the method employed in teaching them. From the standpoint of the majority of the Committee, each secondary school subject was assumed to have equal value with any other, if properly taught. It was, therefore, natural to assume, if a pupil manifested a strong aversion to Latin or mathematics, that some other equally well taught subject could be substituted. (See FORMAL DISCIPLINE.)

Not long after the appearance of the *Report*, students of education began actively to question certain fundamental assumptions implicit in it, and particularly the disciplinary conception advocated by the Committee. It was commonly asserted that Latin, better than any other subject, trained faculties of observation, verbal discrimination, powers of analytical thinking, etc. Equally, it was claimed that the study of mathematics strengthened reasoning powers and greatly improved the capacity for systematic generalization. A series of critical articles, as well as certain investigations in psychological laboratories, tended during the last decade of the nineteenth century to unsettle existing preconceptions regarding mental discipline; in fact, there developed a tendency

to assert that mental training should be a secondary consideration in the teaching of any subject, and that the subject itself should involve a content of knowledge or other power-producing material which should justify it and that, in the course of its presentation, mental training would follow as an accompaniment.

Finally, in recent educational theory there has grown up an increased belief in the wisdom of adapting education to the individual. This represents a considerable departure from an older theory of education, that the individual should be fitted to a given field of subject matter. This change came about, partly, from the causes already presented. It was found that not only the interests, but the needs and capacities of secondary school pupils vary greatly. Furthermore, it was found that the important end of education was to prepare individuals for some field of activity wherein that which was learned in the high school would find application, either as culture or vocational power.

The foregoing influences resulted in the development of the so-called elective system. It is true that, from its beginnings in the academy, the secondary school program had been somewhat elastic, but its elasticity had assumed the form of alternative courses, each course, however, representing a fixed and unvarying demand on the pupil. Naturally, alternative courses varied mainly in their demands for foreign language and for science, English and mathematics were usually prescribed subjects.

The elective system, however, carried the matter of alternative subjects to the point of allowing each pupil, within the limits of the range of subjects presented by the school and the other inherent restrictions of program, substantially to make up his own course. From the standpoint of the school or the pupil, the important consideration was not always so much the subjects which could be taken as those which could be omitted. During the last years of the nineteenth century and the first decade of the twentieth, the literature of secondary education was filled with discussions of the elective system. It was felt by some that it represented a demoralizing tendency in that it weakened the educational conception of discipline through the more difficult subjects. Educational conservatives feared that it meant a persistent discounting of classics and mathematics. They apprehended a rapid development of the more vocational studies, and denied that the individual pupil had any capacity for self-direction in the choice of a program of studies. They asserted that, from the standpoint of the best development of the individual, it was highly important that certain fields of culture should be opened to him, even by compulsory methods. In only a few schools did the theory of free election of subjects make much progress. In these instances the graduation of the pupil was made to depend upon the

accomplishment of a certain number of units of work, but without reference to any specific subjects. He might omit history or mathematics, no less than a foreign language or a branch of science. More commonly the system took the form of a certain number of prescribed studies, with a considerable range of alternatives or options from which the pupil could choose. In the case of some large high schools, for the requirement of specific subjects, there was substituted the demand that, for graduation, a minimum number of units of accomplishment in foreign language, science, history, etc., should be presented, the pupil, however, retaining the privilege of electing among the various subjects in science or history as the case might be.

As a rule, few of the apprehended evils of the elective system have developed in practice. There has been an increased tendency to induce the pupil to make his selections not only with the approval of some advisory teacher, but of parents as well. The limitations of the school curriculum, even in the larger schools, have acted as an important barrier to free election. Furthermore, the fact that a considerable number of students anticipate entering college where the entrance requirements are more or less prescribed has prevented anything like a free use of possible electives.

While the tendency is still to extend the possibilities of election of secondary school subjects, it is nevertheless true that important underlying problems must be solved before an adequate discussion of election is possible. There yet exists no satisfactory theory regarding educational values, especially of secondary school subjects. Quite universally, for example, algebra and geometry are prescribed for both boys and girls in secondary schools. Neither experience nor the tests of educational laboratories serve yet to demonstrate the superior value of these subjects. The same may be said to be true of the foreign languages so far as their training value is concerned. The science subjects have undergone steady modification in modern education, becoming more formal and rigid. There is yet no satisfactory evidence that, as now taught, these sciences contribute in an important way to either culture or practical capacity in greater degree than other possible subjects.

In prescribed programs it is the tendency to require subjects such as foreign language, mathematics, and science, which are most fully organized and which lend themselves most satisfactorily to traditional methods of pedagogic treatment. Until, however, there exists more satisfactory knowledge regarding educational values, it will be difficult to treat the subject of the elective system with anything like finality. It can be easily seen that the arguments for and against election hinge upon the theory of educational values and the capacity of a school to effect individual programs

adapted to the various pupils. If we believe that a limited number of well organized secondary school subjects give either practical capacity, cultural insight, or mental training to be equaled in no other way, then it is a fair assumption that the school program should make these subjects prescriptive. There is little place for election, since the self-knowledge of the pupil and the experience of his parents are altogether insufficient to offset the results of the constructive effort which has gone to the making of the programs. If, on the other hand, we are inclined to believe that the educational values of certain subjects have been greatly exaggerated, and that what the pupil shall study is of less importance than his interest in the subject and the methods employed in teaching it, then it can easily be seen that satisfactory arguments can be made for allowing a part selection on the part of the pupil himself.

Other factors naturally enter into the discussion. Freedom of election means, naturally, that popular teachers will be sought and unpopular ones avoided, — a result which may tend to demoralize administration, and may or may not tend to promote more effective pedagogical methods on the part of the teachers themselves. It is believed that free election would tend to promote the study of practical subjects, at the expense of the more cultural, but again the relative educational values of the two types will be disputed. It is highly probable that a more extended analysis of the subject of election will have to wait a fuller and more scientific formulation of educational theory, as applied to secondary school studies.

There are many reasons for believing that the high school as at present organized contributes certain types of definite training more effectively than it develops culture and appreciation. On the other hand, the greatest deficiency of existing high school programs seems to be their incapacity to produce results of a persistent nature, for example, the study of a foreign language or of mathematics, even when well carried on, fails largely in the face of later demands, the general goal aimed at is not realized. Distinctions will have to be made among various high school studies, with a view to determining the specific principles or purpose which each should serve in a program of fairly well defined educational ends, and in adapting to each subject its own suitable method. This may be illustrated in the case of English. One object of the teaching of English in the high schools is undoubtedly efficiency of expression, both oral and written. Another object, however, and quite distinct from the above, is appreciation of good literature. It seems highly probable that these two ends will have to be attained by radically different methods. The same distinction will apply to certain of the sciences, when pursued from the standpoint of application in vocation

on the one hand, or service in general culture on the other.

The general discussion of the elective system has probably greatly promoted interest in the problems of educational values. It brought subjects into competition, as it were, in a definite way. Until, however, more knowledge is available, many educators will assume that the choices made by the pupil, even when dictated by whim and caprice, may, and, so far as he is concerned, will be no worse than the choice made by a more or less inflexible system which not only fails to take account of him as an individual, but which, to a large extent, has had its origin independently of the study of any group whatever of actual living individuals.

**Six Years' Course of Study** — The fact that the American secondary school, unlike similar schools in Europe, takes the pupil at fourteen, or on the completion of an elementary course extending over eight years, is to a certain extent one of the effects of the historical development of American education. The common school or the elementary school was first established, and, in order to accomplish a full measure of general education, it involved eight or nine, and sometimes ten grades, each a year in length. The typical American elementary school of to-day consists of eight grades, and carries the average pupil from the age of six to the age of fourteen. The first secondary schools — the Latin-grammar school and then the academy — partook something of the character of European secondary schools, in that they maintained preparatory classes in which attention was early given to some secondary school studies. The public high school, however, was almost universally designed to succeed the elementary school course, and to build on it. As a consequence, admission to the high school everywhere requires the completion of an eight-year elementary course, and brings the pupil in at approximately fourteen or fifteen years of age.

This situation has obvious defects. It cannot be insisted, of course, that all American children, or even any considerable number of them, should complete the high school course of study. For those who do, however, the postponement of the beginning of foreign language study, as well as of algebra and geometry, works undoubted harm. For the boy who is to go through high school and into college, there can be little doubt but that the years between twelve and fourteen under the present system of schooling are largely wasted, at least, when viewed from the standpoint of the mastery of particular studies which should assist in the higher schools. The attention given to this subject in recent years has led to a fairly widespread demand for a six-year course of study in the high school, which should take pupils at approximately the age which is becoming customary in some European countries, and which especially should aid them to begin the study of foreign language at

a time when the vocal and auditory organs are still plastic. The administrative difficulties have been so great, however, that only in rare instances has the experiment been tried. The chief difficulty is found in the unwillingness of the American people to permit either a differentiation of schools or a differentiation of classes of studies before the elementary school course has been completed. On the other hand, there is little tolerance for the prescription of foreign language study for all pupils in the upper grades of the elementary school. The result has been that, while a considerable literature has been produced bearing on the desirability of extending high school studies and high school methods downward, very little of a practical nature has been accomplished.

The problem is now being approached in some cities in a different way. It is recognized that the boys and girls from twelve to fourteen years of age possess certain distinctive characteristics and educational needs, which should separate them from the primary school which has preceded. In not a few cities it is now customary to group the upper grades in what are sometimes called intermediate schools where favorable opportunities may be given for manual training, domestic science for girls, commercial studies, and, in a few instances, foreign language. While few of these schools have reached the point of differentiating their courses, there can be no doubt that in a large number of instances they are ready to do so, if public opinion responds favorably. One of these schools in a Massachusetts city (Fitchburg) now receives pupils on the completion of the sixth grade, and admits them to any one of four courses. Certain studies, such as English, history, geography, and music are common for all, and are taken jointly in the classes. Certain other studies are alternative, and it is on the basis of these that the courses are distinguished. For example, boys who wish it may take two hours of manual training per day, and thereby become members of the industrial arts course; for them the arithmetic and drawing will also be somewhat specialized along the lines of the industrial arts. Another group of boys and girls, instead of manual arts, may take a foreign language, the beginnings of algebra, geometry, and English history. This is obviously a high school preparatory course, and may legitimately be regarded as part of a six years' high school course, which it is hoped in time may become five years in length, thus admitting pupils to college one year earlier. A third course offers to girls two hours per day of household arts, the subject being treated very broadly, with related history and science. A fourth course, known as the commercial course, offers opportunities in typewriting, commercial arithmetic, the beginnings of book-keeping, and a line of work wherein commercial geography and industrial history are combined.

It is not intended that any of the above

courses shall be vocational, but that some of them shall draw from the world of vocational activities studies and problems that are significant and vital to the pupils concerned. Neither is it intended that any of the above courses shall be a blind alley, in the sense that it leads to no higher work. Nevertheless, it is obvious that a pupil from the industrial arts course who wishes to go through high school will have to take additional time in order to meet the language requirements.

The above represents a type of development in educational administration which will probably realize the purposes of the so-called six years' course of study, without involving premature differentiation of classes of pupils on the basis of their ability or economic state in life. It will afford an opportunity to make of foreign language study something more effective than is possible at the present time. It will promote departmental teaching, and the introduction of college-trained teachers in the higher grades.

D S

**Maintenance and Support** — It is only within recent years that any real attempt to aid in the maintenance of secondary schools has been made by the states or counties, and the giving of such aid, though becoming more common each year, is still not a general feature of our state school systems. (See APPORTIONMENT OF FUNDS.) In some states no distinctions are made between common or elementary schools and high or secondary schools, either in statistics or in finance. Communities which maintain secondary schools are placed on the same footing as communities that do not, with the result that the maintenance of a high school is purely a local burden. Secondary education is, comparatively speaking, so recent an undertaking that most states have not as yet made any definite provision for the equalization of its advantages. These schools, however, have recently grown greatly in popular favor, due in part to the need of increased education to meet the changed conditions of life, to the introduction of new studies and methods of instruction, and to the changed conception of the purpose of secondary instruction. The result is that the high school is destined soon to be a regular and a necessary part of our systems of public instruction, and that high school facilities will be provided for all. This change in attitude is certain to add force to the demand for some form of general aid for secondary, as well as for elementary instruction. The maintenance of elementary schools and a state university, and the refusal to help in the maintenance of secondary schools, is not a logical position for a state to assume.

The expense of maintaining secondary schools is so much greater than that for elementary schools, due to the need of better trained and more expensive teachers, smaller classes, the smaller number enrolled, and more expensive teaching equipment, that the need of some

general aid is apparent, if they are to be developed at all generally. This is accentuated by the fact that the cost for elementary schools is also increasing, and that the money now at hand and originally intended for the support of elementary schools alone is rapidly proving insufficient for the support of both classes of schools. Many communities are at present trying to support a full twelve-year school system with funds hardly sufficient to properly maintain the elementary schools.

Such provision as has been made by the different states extends from mere permission to communities to form such schools and to tax themselves to pay for them, — which is analogous to the first legislative permission to the people of a community to organize a taxing district and tax every one for the support of an elementary school, — to a general state tax levied for the support of secondary education and apportioned and used for that purpose alone. The first is the mere beginnings and the second is the culmination of the process, and between the two are many intermediate plans for the granting of some degree of aid to secondary schools.

Mere permission to cities, towns, districts, and unions of districts to form a high school and to tax themselves to pay for it, must be regarded as the first step in the process of the evolution of a system of general aid to secondary education. A petition and an election are the usual preliminary steps, and after the formation of the high school district an annual local tax, frequently of a limited amount, is permitted for the support of the school. Sometimes such schools are under the control of a separate school board, known as a high school board (*qv*), and sometimes the board which has control of the elementary schools merely takes charge of the high school also. A number of states have taken this first step, but have not gone further. The next step is found where the principle of local support is retained, but the taxing area is extended to a larger area, as to the county as a whole. In states which have taken this step, common in the West, we find the county high school. The common features of these permissive high school laws are the necessity of a petition asking for the submission of the question of the formation of a county high school to a vote of the people, a special election to decide the question, the appointment or election of a board of trustees for the school, an annual county tax for support, free tuition in the school to all residents of the county, and usually provisions for the dissolution of the school, after a time, if desired, by vote of the people. With the formation of a second county high school at some other place, or with the segregation of a certain district or districts to form a local high school separate from the county high school, the process of subdivision of the high school district has begun.

The next step in granting aid to high schools is taken when the state begins to make a series of grants, or subsidies, to aid secondary schools. A number of states have taken this step, though the plan has been worked out but poorly in most of the states. The granting of such aid naturally stimulates the development of high schools, and if the appropriation to pay the grants or subsidies is not of a flexible form, and one that increases with the growth of the schools, the result will be a failure to provide the aid intended. Where a definite legislative appropriation has to be made to pay the grant, as in a number of the states, the appropriation is likely to fail to increase as fast as the schools do, and the result is a forced scaling down of the grant. In Minnesota, for example, the state aid determined upon was \$1000 to each properly approved school, but the schools increased so much faster than did the appropriation that the grants were scaled lower and lower for a number of years. The same thing happened in Pennsylvania. This gives an uncertainty to the value of the grant which makes the method less desirable than other plans that can be devised. The method, also, places all of the premium on the mere existence of the school, but none on the employment of a sufficient number of teachers to do the work properly, or on the addition of such subjects of instruction as will make the school of greater worth. A school with only a single "classical course" stands on the same footing, so far as state aid is concerned, with another school which employs relatively more teachers and offers two or three courses of instruction. The second school will cost much more per capita to maintain, assuming that the two are located in somewhat the same kind of communities, and will attract more students and will render a much larger educational service, but under the lump subsidy plan of aid it will receive no greater reward than the smaller and poorer school. If it is worth while to aid secondary education at all, then the state ought to so apportion its aid as to place a premium on the giving of instruction under good educational conditions. The subsidy method places no premium on growth or better instruction and makes the position of the state as to the improvement of existing conditions a purely negative one. The subsidy method marks the beginnings of state aid, and ought to be abandoned as soon as possible for a better form of assistance. If the subsidy plan is to be used, it ought to be graded both as to years and character of instruction offered, and the power to grant, scale down, or withhold the grant ought to be centralized in some responsible educational body, possessing powers of inspection. The one marked merit of the subsidy plan, where graded subsidies are employed based on the number of years of instruction offered, is that it places a premium

on the development of two-year and three-year high schools, as well as four-year schools. Any good instruction beyond the grammar school, even if for only one year and taught to only a few pupils, is a stimulating influence which reacts most favorably on all lower instruction. Two-year high schools frequently develop into four-year high schools, and communities are usually able to provide two years of instruction before they would be able to provide a fully equipped four-year high school.

California and New Jersey stand as examples of states which have reached the culmination of the process. In both states the high school has been adopted as a part of the state school system, though by a somewhat different method in each. In California the complete adoption of the high school has come through the provision of separate and special taxation for the support of high schools and by a constitutional provision that the income from the state school fund, and the proceeds of all previous taxation, can be used only for the support of elementary schools. This forever prevents the robbing of the elementary schools to maintain high schools, a process which goes on in many of our states. For the support of the high schools of the state a special state tax for high schools is levied and apportioned. To keep the income for this purpose constantly up to the needs of the schools, it has been provided that the tax to be levied shall be determined annually by multiplying the number of high school pupils in average daily attendance in the state the preceding year by \$15, which requires a state tax of approximately  $1\frac{1}{2}$  mills. This is then apportioned to all approved high schools in the state on the following basis: one third equally to all schools, regardless of size, and two thirds to all schools on the basis of average daily attendance. The apportionment plan could be improved still further by making a partial apportionment on the basis of the number of teachers actually employed. Length of term is here a negligible factor, because all schools are required to maintain a term of at least 180 days to receive any aid. New Jersey offers an example of the complete incorporation of secondary education into the state school system. Here the apportionment of school funds is made to high schools as to elementary schools, on the teacher basis, viz. \$400 for every teacher actually employed in each high school, and the remainder on a basis of so much per pupil per day in actual attendance, in all kinds of schools. The apportionment of state aid to a high school is thus made on a plan similar to a kindergarten, primary school, or grammar school. All belong to the same state school system, all share in the apportionment of funds, and all are paid out of a common fund. The value of such a plan, if sufficient revenue can be obtained, is

at once evident. High schools cease to be a separate part of the school system, and become an integral part of the system of public instruction. The state then rewards a community's efforts according to the amount of instruction provided, as measured by the number of teachers employed, and according to the actual amount of work done, as measured by the attendance upon the instruction offered. If a rural union school will provide only the ninth-grade work, and thus give the boys and girls in the rural districts a taste of something beyond the common school branches, the state will reward such an effort by a grant for both the teacher employed and the extra attendance resulting. If a village will employ one additional teacher and provide two years of high school instruction, the state will similarly reward such effort. To the large city school the state offers a similar standing premium on additional effort, every new teacher and line of work added receiving additional aid. The simplicity, justice, and automatic adjustment of the plan to community needs and efforts are strong points in its favor. One thing, though, which ought always to accompany such a complete incorporation of the high schools into the public school system, is a proportional increase of available funds, with provision for an automatic increase. There is no wisdom in incorporating high schools into the state school system, if the elementary schools are to be made to pay the bills.

Such an incorporation of high schools into the system of public instruction is not possible if the census basis of apportionment is used (See article on APPORTIONMENT OF SCHOOL FUNDS.) The essential unit in higher, as in elementary instruction, is the teacher who must be employed to teach the pupils, and not the number of pupils alone. Under a combination of teacher-actually-employed and attendance bases, as used in New Jersey, the high school is placed on the same basis as any other school, and thus becomes an integral part of the system of public instruction. The California and the New Jersey plans are the best that have been evolved for the support and incorporation of high schools. The California plan is especially meritorious in that it provides a separate and a large fund for aid to secondary education, and the New Jersey plan is especially commendable in that it establishes one organization. In view of the possibility of a reorganization of the plans for upper grammar grade and high school instruction (see article on INTERMEDIATE HIGH SCHOOLS), this must be considered an important gain. If in the future a six-year high school should prove to be a desirable addition to our school work, the present somewhat rigid classification in some states would stand in the way.

Another form of support for high schools comes in the attempt to abolish tuition fees for

those children who do not happen to live in high school districts. Children who live in cities, towns, or districts which maintain high schools of course have free high school tuition, but children who live in adjoining districts which are not a part of some high school district are almost invariably forced to pay a tuition charge, and this is frequently made very high for the purpose of reducing the attendance of such outside pupils. The unfairness of such tuition charges is at once evident, and a number of states have attempted to do away with them. The method employed in doing so varies in different states. In Indiana the pupil applies in person for a transfer, which, if granted, carries with it the payment of fees; in Ohio the township from which the pupil comes is directed to assume the fees, in Wisconsin a bill is presented by the school receiving the pupil to the district from which he comes, and then a tax is levied to pay the bill; in Massachusetts the town in which the pupil resides must pay the tuition charge, unless it is one of a class of poorer and smaller towns, in which case the state pays the bill, and in Connecticut the state reimburses towns for two thirds of the tuition paid, and will also pay one half of the cost of transportation. In California a very simple and very effective method has recently been worked out, whereby every child in the state has free high school privileges. The county superintendent of schools of each county is required to estimate annually the number of probable high school pupils for the coming year who live in non-high-school territory, and then to have levied by the county authorities a county high-school-tuition tax sufficient to pay the tuition charge of all non-high-school district pupils in the nearest or most convenient high school. As the state pays the high schools for all pupils in average daily attendance, this includes state aid to all. It remains purely optional with a district now whether it will form a high school of its own, join a high school district already in existence, or pay its tax for the tuition of non-high-school pupils. In any case the cost is paid by general taxation, levied on all property for high school purposes.

**HIGH SCHOOL BOARDS** — Boards of control having charge of the general management of high schools. Such boards are found in states where the organization of high schools, separate from elementary schools, has been provided for in the laws. This is commonly found in the West. In many Western states the law provides for the organization of district high schools, town high schools, and city high schools, by action of the people or of the Boards of Education or Trustees for such districts, towns, or cities; and also for the organization of union high schools by the joint action of two or more boards or districts, and county high schools by vote of the people of an entire county. In the first case the Board of Education for the elementary schools of the district, town, or city becomes the high school board as well, and, except in so far as the finances of the two schools are usually kept separate, the two classes of schools are managed as a unified system by the one board. The added high school merely becomes a part of the public school system of the district, town, or city, and has no separate management, except in some states where high school money must be levied and paid out separately from elementary school funds. In the case of union district high schools a separate board of education is elected to take charge of the high school, usually consisting of representatives from each of the districts so uniting to form the union high school. In the case of county high schools, the County Board of Education, where such a body exists, is usually made, *ex officio*, the high school board for all county high schools, and where it does not

## HIGH SCHOOL FRATERNITIES

exist a special high school board is elected. In many of the Southern states, and in some of the upper Mississippi Valley states, county high schools, partly or largely agricultural in type, have been created within recent years. These are supported by general county taxation and state aid grants. These schools are under the county boards of education, or special county high school boards, elected or appointed for the special purpose. The county superintendent is commonly a member, *ex officio*, of such high school boards. E. P. C.

### Reference:—

The California School Law, *High School Act*, contains a good explanation of this form of separate high school management, and the North Carolina or North Dakota School Laws describe the county high school of agriculture type of high school management.

**HIGH SCHOOL DISTRICTS** — School districts organized primarily for the establishment and maintenance of a high, or secondary school. Sometimes these coincide with existing school districts, formed for the maintenance of elementary schools, as in towns or cities; sometimes they are larger and include two or more elementary school districts, and not infrequently a dozen or more elementary school districts. Sometimes the high school district is the same in size as a township, and sometimes, especially in the West, the same in size as a county. See DISTRICTS, HIGH SCHOOL BOARDS, HIGH SCHOOLS, SUPPORT OF. E. P. C.

**HIGH SCHOOL, EVENING** — See CONTINUATION SCHOOLS, INDUSTRIAL EDUCATION

**HIGH SCHOOL FRATERNITIES** — This term applies to organizations of high school pupils modeled in imitation of the Greek letter societies in colleges. (See FRATERNITIES.) The high school secret society is usually designated by a Greek letter symbol taken from the initials of the motto of the club. Rites of initiation, grips, pass words and the other usages of secret organizations are common features.

These societies began to appear about the year 1890. At first the movement attracted but little attention, although in some instances high school principals and teachers gave sympathy and support, but in most cases wherever any attitude was assumed by the school authorities, it was in opposition to such societies. The number of organizations increased rapidly, and with this increase came a more thorough organization. The society chapters began to form national organiza-

## HIGH SCHOOL FRATERNITIES

tions. Instead of using the homes of the members as places for the gatherings, many chapters secured rooms in office buildings, wherein meetings were held. The expense of membership increased. Serious abuses appeared in the practice of the rites of initiation and in the influence of the societies upon high school discipline and scholarship. As a result, the subject of high school secret societies came to attract the earnest attention of schoolmen, of superintendents, and of various educational organizations throughout the United States. One of the most notable investigations was that conducted by the National Education Association through a special committee, reports from which were presented at the 1904 meeting at St. Louis and at Asbury Park in 1905. In 1904 a report was made by a committee on the influence of fraternities in secondary schools to the eighteenth Educational Conference of the academics and high schools in relation with the University of Chicago. Under the auspices of the Massachusetts Council of Education a study of high school fraternities and sororities was made and a report presented to that body in 1905. The consensus of opinion in each case was that the high school secret society, whether a fraternity composed of boys, or a sorority composed of girls, is an undesirable element in the life of the secondary school. The reasons adduced are as follows:

(1) The influence on the school is injurious by reason of the division of the school into cliques, the introduction of petty politics, and the loss of interest on the part of pupils in literary and other organizations with serious purpose. (2) The pupil suffers injury, the protection of secrecy gives opportunity for much evil to be practiced in the fraternity rooms. There is a decline in the spirit and standards of scholarship of the individual pupil. (3) There is no real need for such organizations in the high school because conditions are so different from those in college. (4) Such societies set up improper standards, and counteract the influence of the teacher. (5) They constitute a source of danger in the proper government of the school.

As a result of the findings of these various committees and of the expressions of opinion from men prominent in the work of education, boards of education have undertaken to lessen the influence and power of these societies or to eliminate them entirely from school life. Often such action has been met by determined opposition on the part not only of pupils, but of parents. In several instances the decrees of boards of education have been resisted and an appeal made to the courts. A notable instance is that of the Seattle High School Fraternity, before the Supreme Court of the state of Washington. The directors of school district No. 1 in Seattle had established

## HIGH SCHOOL FRATERNITIES

a rule whereby the use of the name of the Seattle High School by a fraternity was forbidden, and pupils were prohibited from becoming members of any secret society under penalty of being deprived of all privileges of the school outside of the classroom. A pupil so punished brought suit through his guardian to compel the school directors to restore him to these privileges. The judge sustained the action of the school committee. In several other cases the right of the school authorities to inflict various penalties on pupils for membership in secret societies has been sustained by the courts.

In a number of states drastic legislation has been passed with a view to controlling or abolishing the secret society in the high school. In 1907 Indiana, Kansas, and Minnesota passed laws of this nature. In addition to recourse to legislation, principals, superintendents, and school committees have undertaken in different cities to deal with the fraternity question by appeal to public opinion and by regulations forbidding the use of the schoolrooms, the school name, or the recognition of the organizations in any way in connection with the school publications. In some instances the cooperation of parents has been secured and the societies eliminated. In other cases the pupils themselves have joined with the teachers and agreed to give up the organization. The influence of the secret societies in the school itself has been successfully met by the encouragement on the part of the teachers of clubs and organizations of pupils each of which is based upon some real and valuable interest, such as debating, publication of school papers, glee clubs, and French and German circles. Under proper guidance membership in such organizations soon comes to be valued and esteemed by the pupils, and the secret society to some extent loses its charms.

The high school fraternity has its defenders not only amongst the pupils, but among parents and in the general public. It is claimed that such clubs constitute a natural and fitting opportunity for the expression of the social instincts of young people of high school age, and that the members learn important lessons in cooperation in managing the affairs of the society and in conducting various enterprises in the name of the club. It is pointed out by these advocates of the system that the abuses of which so much complaint has been made are incidental, and that under proper supervision and control such evils need not exist. They argue further that in schools where all the members are admitted to such societies there will not arise feelings of rivalry and jealousy such as exist where some members are left out in the choice for these organizations. The consensus of opinion is, however, against the existence of such exclusive sets or coteries of pupils in a public institution supported by

taxation, because their very presence is inconsistent with a truly democratic spirit

**HIGHER EDUCATION** — A term somewhat loosely used with different connotations not only in different countries, but in each individual country. In England it is used by the Board of Education to refer to "education other than elementary" (See Education Act 1902, Pt III, § 2); but in Graham Balfour's *Educational System of Great Britain and Ireland* (Oxford, 1903) higher education refers to "that general training given in Universities and University Colleges," while the most recent work on secondary education bears the title *Higher Education of Boys in England*

(Norwood, C, and Hope, A H, London, 1909). The same confusion exists in Germany. Lexis, *Das deutsche Unterrichtswesen*, uses the term *Das höhere Schulwesen* to refer to the secondary school system, while Fick, *Auf Deutschlands Hohen Schulen*, deals entirely with the German universities, and the term *Hochschule* always signifies an institution of university grade. In southern Germany this attitude is well marked by the designation of secondary schools as *Middle Schools (Mittelschulen)*. The German use is also prevalent in the United States, where higher education refers to such education as is given above the high schools. Thus the title of Chancellor Brown's work, *The Making of our Middle Schools* (New York, 1903), is intended to mark the place of secondary education as intermediate between elementary and higher, and this use is more clearly emphasized in various essays on "Higher Education," which deal with the education in the college and university. In France the term *Éducation Supérieure* definitely means education beyond the secondary schools.

See MITTELSCHULE.

#### HIGHER NORMAL SCHOOL OF FRANCE — See NORMAL SCHOOLS

**HIGHLAND COLLEGE, HIGHLAND, KAN** — A coeducational institution which grew out of the Indian Mission School. Opened as a university in 1857, it is under the auspices of the Presbyterian Synod of Kansas. Academic, collegiate, commercial, and music departments are maintained. The entrance requirements are equivalent to about fifteen units. The degrees of A B and B S are conferred on the completion of the necessary courses.

**HIGHLAND PARK COLLEGE, DES MOINES, IA** — A coeducational institution founded in 1889, now under the control of the Presbyterian Church. It maintains a normal college, academy, colleges of liberal arts, law, engineering, pharmacy, music, oratory, commerce, a correspondence school, and a summer school. The college gives degrees of A B and B S, on three-year courses. Lower credits are required for admission to the three-year engineering courses. There is a faculty of sixty members.

**HILDEBRAND, HEINRICH RUDOLPH** (1824-1894) — German philologist, who exercised considerable influence on the teaching of German in elementary schools. Born in Leipzig, he attended the Thomasschule, and thence proceeded to the university. He returned to his old school in 1848, and proved a very capable teacher. His interest, however, was mainly in linguistics, and as early as 1859 he began to assist Jacob Grimm in the edition

of his dictionary, and on his death became one of the coeditors of the work. In 1868 he resigned his position at the school, and in 1869 became extraordinary and in 1874 ordinary professor in the University of Leipzig. His chief work was *Vom deutschen Sprachunterricht in der Schule und von deutscher Erziehung und Bildung überhaupt* (*Teaching of German in the School and German Education and Culture generally*, 1865), in which he recognizes the cultural and national value of training in the vernacular. He emphasizes the importance of oral expression in the schools and the teaching of the significance and history of words, believing, as he did, that language in its development presents a composite picture of national history and growth. For similar reasons he would not neglect dialect forms, the embodiment of the thought and life of the people. His other works are *Beiträge zum deutschen Unterricht* (*Contributions to the Teaching of German*, 1886), *Gesammelte Aufsätze und Vorträge zur deutschen Philologie und zum deutschen Unterricht* (*Collected Essays and Lectures on German Philology and Instruction*, 1890).

**HILL, FRANK ALPINE** (1841-1903) — Superintendent of public instruction in Massachusetts; was educated at the Biddeford, Me., High School and at Bowdoin College, graduating in 1862. He was principal of secondary schools in Maine and Massachusetts from 1862 to 1893, when he was chosen secretary of the State Board of Education of Massachusetts, which position he filled for ten years. He was active in the organization of district school superintendents in the state. His educational writings include *Seven Lamps of the Teacher* (1902), a textbook on United States history (with John Fiske), and numerous essays on educational subjects. W S M

**HILL, JOHN HENRY** (1791-1882) — Founder of the Hill School at Athens, Greece; was graduated from Columbia University in 1807. He went to Greece as a missionary in 1830, and two years later established the Hill School at Athens. This institution, which includes elementary, secondary, and normal departments, had large influence on the sub-

sequently organized municipal schools at Athens and the national schools of Greece. He translated a number of American and English books into the modern Greek. W S M

**HILL, THOMAS** (1818-1891) — Twentieth president of Harvard University; was graduated from Harvard. He was president of Antioch College from 1859 to 1862, succeeding Horace Mann (*qv*), and of Harvard University from 1862 to 1868. His educational works include an *Arithmetic* (1845), *First Lessons in Geometry* (1855), *Liberal Education* (1855), and *True Order of Studies* (1859). He invented the occulator and other contrivances for the teaching of mathematics. W S M

See HARVARD UNIVERSITY

**HILL, THOMAS WRIGHT** (1763-1851) — English educational reformer, born at Kidderminster, Apr. 24, 1763, the son of a baker and dealer in horse corn. Hill received his early education in a school at Market Harborough kept by a Nonconformist minister. In childhood he showed a strong taste for literature and physical science. At the age of fourteen he was apprenticed to a brass founder in Birmingham, where he became a member of Joseph Priestley's congregation, and threw himself with energy into the work of Sunday school teaching in connection with Priestley's chapel. He invented a system of shorthand, and devised a plan for the representation of minorities by a proportionate vote. Hill was the father of a distinguished family: viz. Matthew Davenport Hill (1792-1872), reformer of the criminal law, friend of Jeremy Bentham (*qv*), colleague of Mary Carpenter (*qv*) in the establishment of reformatories, and active advocate of the boarding out of pauper children; Edwin Hill (1793-1876), writer on the currency and an ingenious inventor who improved the machinery for the manufacture of stamps; Rowland Hill (1795-1879), who planned the scheme of penny postage and by persistent advocacy forced it upon a reluctant and ungrateful government; Arthur Hill (1795-1879), schoolmaster, whose son, George Birbeck Hill, was editor of Boswell's *Life of Johnson*; and Frederic Hill, Inspector of Prisons in Scotland and afterwards Assistant Secretary in the Post Office.

Hill's school in Birmingham was the result of the joint labors of himself, his wife, and four of his sons, Matthew Davenport, Edwin, Rowland, and Arthur. It is difficult to assign the original ideas which underlay its organization and discipline to the several members of this family group. Perhaps the greatest

credit should be ascribed to Rowland, who, greatly influenced by Maria Edgeworth's stories, began to teach in his father's school at the age of twelve, distinguished himself as a teacher of mathematics, and, at the age of seventeen, undertook the entire management of his father's money affairs and at last cleared off his debts. Rowland recorded in his *Journal* that it was the height of his ambition "to establish a school for the upper middle classes wherein the science and practice of education might be improved to such a degree as to show that it is now in its infancy." A new house was built for the school at Hazelwood in the outskirts of Birmingham, and its educational method became famous as the Hazelwood system. Special attention was paid in the curriculum (a) to the teaching of languages in which the "natural method" was employed, i.e. both dead and modern languages were taught in great measure orally and by conversational methods, the abstract technicalities of grammar being relegated to a subordinate place, (b) to elocution, with the purpose of refining literary taste and teaching right enunciation and inflection, (c) to the art of writing in such a way as to combine beauty and swiftness, (d) to the scientific teaching of arithmetic, including mental calculation and applied geometry and open-air surveying, and above all (e) to the formation of character and to inculcation of right ideas of moral duty, including a sense of civic obligation, the cultivation of social sympathy, and the love of justice. A full description of the aims and methods of the school was published (anonymously) by Matthew Davenport Hill in a work entitled *Plans for the Government and Liberal Instruction of Boys in Large Numbers, drawn from Experience*. This book was epoch-making. It forms one link of a chain of influence, which, beginning with Rousseau's *Emile*, took on English characteristics in the *Practical Education* (1798) of R. L. and Maria Edgeworth (qqv), and subsequently culminated in Stanley's *Life of Thomas Arnold* (1844). The authors of the book show that they are well acquainted with some of the writings of Pestalozzi and also of the older English educational reformers and of the French encyclopedists of the eighteenth century. Shortly after its publication (in 1822), Hill's book was reviewed by De Quincey. It fascinated Jeremy Bentham, and secured for the school the enthusiastic patronage of the Benthamite group. Numbers of pupils were sent to the school from the newly founded republics of South America and from Greece. A school was established in Stockholm in imitation of it. There is little doubt that the educational discussions provoked by the publication of the book had considerable influence upon the mind of Dr. Arnold, and bore fruit in his work at Rugby, 1828-1843. In 1827 the main body of the school was transferred

from Hazelwood to Bruce Castle, Tottenham, near London.

As for the mechanism of their plan of school government, they recognized their indebtedness to the monitorial tradition of medieval education and of the English Public Schools, but disclaimed any debt to Bell and Lancaster, whose services they recognized, but whose purpose they regarded as dissimilar. They applied somewhat inconsiderately to school conditions the machinery of elective local government, thus anticipating later experiments in the formation of the school city. Their ideal was a judiciously supervised, self-governing boy democracy. The details of their scheme were overintricate and a little doctrinaire. Joshua Toulmin Smith (1816-1869), himself a native of Birmingham, and, like the Hills, a member of the Unitarian Church, shared the same antiquarian enthusiasm for pure local democracy. But the vital significance of the educational doctrine of the Hills lay in its emphasis upon the moral and spiritual power which may be developed through the wise organization of corporate life in a skillfully ordered community. This is the conception which appealed to Thomas Arnold (qv), and to which he gave effective development at Rugby, with far-reaching results upon higher education throughout the world. The Hills were thus among the first to give utterance in the sphere of education to the new collectivist ideal which arose in reaction to the individualist presuppositions of eighteenth-century rationalism and of the French Revolution. One defect of their scheme, as of Dr. Arnold's, was that their school bore no organic relation to the public life of the adult community which it served. The Hills in their private school, like Dr. Arnold in the endowed school at Rugby, were, though intensely civic in purpose, unconsciously separatist in their influence upon subsequent educational organization. But in the circumstances of the time, this was inevitable — the close connection of King Edward School, Birmingham, with the Church of England making it natural that Nonconformist parents of the middle ranks should support a private school more in accordance with their convictions, just as the presuppositions of the then central government made it natural that Arnold of Rugby should resist any extension of state control over the religious and intellectual life of the great Public Schools. A chief part of the work of recent educational reformers in England has lain in the attempt to bring the conception of corporate school life (which is largely due to the work of the Hills and of Dr. Arnold) into living relation to the educational systems under government and local authorities.

A second defect in the system of the Hills, as also in that of Arnold of Rugby, was that it tended to induce precocity of moral sensitiveness. A former pupil, W. L. Sargant, wrote

of it: "By juries and committees, by marks and by appeals to a sense of honour, discipline was maintained. But this was done at too great a sacrifice. The thoughtlessness, the spring, the elation of childhood were taken from us, we were premature men."

M. E. S.

**HINSDALE, BURKE AARON** (1837-1900) — American professor of education and educational writer; was born at Wadsworth, Ohio, on Mar. 31, 1837, and was educated at the Eclectic Institute (afterwards Hiram College). He was for several years engaged in the work of the ministry. He was president of Hiram College from 1870 to 1882, superintendent of the schools of Cleveland from 1882 to 1886, and professor of the science and art of teaching in the University of Michigan from 1888 to 1900, succeeding William H. Payne (*q.v.*). His contributions to educational journals were numerous, and he wrote a large number of books on education. The latter include *Schools and Studies*, *President Garfield and Education*, *The Art of Study*, *Studies in Education*, *Jesus as an Educator*, *How to Teach and Study History*, *Teaching the Language Arts*, *Horace Mann and the Common School Revival in the United States*, and *History of the University of Michigan*. He published several works on American history and edited the writings of James A. Garfield. He was also active in the council of the National Education Association and the Michigan State Teachers' Association. W. S. M.

**HIPPARCHUS** — The greatest of the Greek astronomers, born at Nicæa in Bithynia, c. 160 B.C. He seems to have studied at Alexandria, but the greater part of his work was done at Rhodes. He was a very careful observer, and he determined the length of the year to within six minutes, the obliquity of the ecliptic to within five minutes, the annual precession of the equinoxes to within eight minutes and eight seconds, and the eccentricity of the solar orbit to within  $\frac{1}{17}$ . He made numerous other important discoveries and laid the foundations for the work of Ptolemy. (See PTOLEMY and ALMAGEST) He may be called the first great teacher of astronomy and the first to place it upon a scientific basis. While trigonometry

(*q.v.*) had made a beginning before his time, he was the first to use it in any large scientific way, and he has therefore been looked upon as entitled to be called its inventor. Geography is also greatly indebted to Hipparchus, since he was the first to locate places upon the earth's surface by means of their latitude and longitude. D. E. S.

### HIPPIAS — See GEOMETRY.

**HIPPOCRATES** (c. 460–370 B.C.) — Greek physician and philosopher, the “Father of Medicine,” born at Cos of a family of priest-physicians, the Asclepiadae. His training he probably received mainly in the famous temple of health (Asclepion) at Cos. He studied under the sophists, Democritus and Gorgias, and under Herodicus, who applied physical exercises to the healing art. He traveled extensively, and practiced in many places. Many stories cluster around his name, the majority, however, are legendary. In a rationalistic age Hippocrates was the first to establish a medical science independent of superstitions and priestcraft and of philosophical speculation. There was no one disease, he held, without a natural cause. Diseases are due to seasons, climates, water, location, air, food, or exercise. The chief remedies for disease are regimen and diet, but there is also an innate restoring essence (*φύσις, vis medicatrix naturæ*). Numerous works are attributed to Hippocrates, but of these only about fifteen are regarded as genuine. His writings are marked by careful observation and broad experience. Many of his medical principles have stood the test of centuries. But his anatomical contributions are naturally of less value, although it would appear from some of the descriptions that he knew something of anatomical dissection. His chief work is the *Aphorisms*, a collection of about 400 sentences on principles of medicine, physiology, and natural philosophy. This has been translated into all the languages of the civilized world. With those of Galen, the works of Hippocrates formed the chief subjects of study in the medieval medical faculties. They were translated in the sixth century into Latin, and although they were lost, a Græco-Latin medical tradition seems to have been established. After the middle of the eleventh century the knowledge of Hippocrates was direct and the *Aphorisms* were translated from Arabic into Latin by Constantius Africanus about 1080. He was especially studied at Salerno and Montpellier, where Rabelais lectured on his works in the original Greek in 1537. How great has been the reverence for the “Father of Medicine” is shown by the fact that the Hippocratic oath is still administered to medical graduates in many American universities (*e.g.* Columbia University). The following is a translation of the oath, which is instinct with the highest ideals for the profession: —

“I swear by Apollo the Physician and Æsculapius, and I call Hygieia and Panacea and all the gods and goddesses to witness, that to the best of my power and judgment I will keep this oath and this contract — to wit — to hold him, who taught me this Art, equally dear to me as my parents, to share my substance with him, to supply him if he is in need of the necessities of life, to regard his offspring in the same light as my own brothers, and to teach them this Art, if they shall desire to learn it, without fee or contract, to impart the precepts, the oral teaching, and all the rest of the instruction to my own sons, and to the sons of my teacher, and to pupils who have been bound to me by contract, and who have been sworn according to the law of medicine.

“I will adopt that system of regimen which, according to my ability and judgment, I consider for the benefit of my patients, and will protect them from everything noxious and injurious. I will give no deadly medicine to any one, even if asked, nor will I give any such counsel, and similarly I will not give to a woman the means of procuring an abortion. With purity and with holiness I will pass my life and practice my art. Into whatever houses I enter I will go into them for the benefit of the sick, keeping myself aloof from every voluntary act of injustice and corruption and lust. Whatever in the course of my professional practice, or outside of it, I see or hear which ought not to be spread abroad I will not divulge, as reckoning that all such should be kept secret. If I continue to observe this oath and keep it inviolate, may it be mine to enjoy life and the practice of the Art respected among all men for ever. But should I violate this oath and forswear myself, may the reverse be my lot.”

Of the works which have been attributed to Hippocrates, the following are regarded as genuine: *On Airs, Waters, and Places*, *On Ancient Medicine*, *On the Prognostics*; *On the Treatment in Acute Diseases*, *On Epidemics* (Books I and III), *On Wounds of the Head*, *On the Articulations*, *On Fractures*, *On the Instruments of Reduction*; *The Aphorisms* (Seven Books); *The Oath*; *The Physician's Establishment or the Surgery*; and *The Law*.

### HIPPOCRATIC OATH. — See HIPPOCRATES.

**HIPPOLYTUS** (d. 236) — A disciple of Irenæus, and the most learned member of the Roman Church in the Ante-Nicene Era. He was the first anti-pope, in opposition to Callistus, but was afterwards reconciled with the reigning pope and revered as a martyr. He was a man of immense literary activity, and he and his works have been the subject of long-continued controversy. They were written in Greek, and consisted of a multitude of treatises, polemic, dogmatic, apologetic, and exegetic. Most of them have been lost. In 1842 the greater part of the *Philosophumena*, only the first book of which had been extant up to that time, was discovered in an ancient monastery upon Mt Athos. At first attributed

to Origen, and later to Caius and Epiphanius, it was ultimately assigned by the unanimous agreement of scholars to Hippolytus. It is a refutation of all heresies by tracing their origin to pagan philosophy and Oriental theosophy. Its author is as uncompromising a foe to the ancient systems of philosophy as Tertullian himself (*q.v.*), and exhibits great acuteness in tracing the relationships between them and the heresies which disturbed the early Christian Church. His work is also valuable as a source-book of history. W. R.

**HIRAM COLLEGE, HIRAM, OHIO —**

Founded in 1850 by the Disciples of Christ as the Western Reserve Eclectic Institute for the education of both sexes. From 1856 to 1861 and from then to 1866 with intervals President Garfield (*q.v.*) was principal and lecturer at the Institute, which in 1867 became Hiram College. In 1907-1908 the Board of Trustees became a self-perpetuating body. The institution maintains a college and departments of music and missionary service. The entrance requirements are fifteen units. Four courses are offered in the college, literary, ministerial, philosophical, and scientific, leading to the degrees of A. B., B. S., and Ph. B. Of 345 students enrolled in different departments 224 took work in the college. The faculty consists of twenty-two members.

**HISTORY.—As a College and University Study.** **Content and Method.**—History is concerned with the past life of man considered as a member of society. It is thus distinguished from biography, which deals only with individuals, and from anthropology, which treats of man as a unit in the animal kingdom, but these distinctions are not absolute, for the history of the individual cannot be cut off from the society in which he lives, and no sharp line can be drawn between the natural history of man and his social history. In a looser sense history is often used to denote any succession of facts, as when we speak of the life history of a plant or animal or the history of the solar system—an extension of the term which arises from the general adoption of the historical habit of thought, which looks upon all things in the universe, not as fixed and stable, but as undergoing a process of change. History

comprises the whole period of the development of human society from the earliest ages for which evidence has been preserved, and includes the various manifestations of the human spirit in art, literature, and religion, as well as the vicissitudes of states and their leaders and the course of economic and social evolution. Certain of these fields are commonly marked off for separate treatment, so that we have the history of language, of literature, of art, of religion, of philosophy, as well as the social and political sciences which derive their material largely from historical records; but such a division is one of convenience only. None of these more special topics can be understood apart from the general course of historical development, and only the historian can bring them into their proper relations as parts of the evolution of civilization. Before this broader conception of history the attempt to limit it to "past politics" is rapidly losing ground, but the life of the state, as the most important social group of civilized man, must remain prominently in the foreground of history, by reason of its intrinsic significance and because on the whole it furnishes the most natural category for the classification of historical facts. History thus stands in especially close relations with political science and economics, not only because it furnishes them with the greater part of their materials, but also because it constantly needs their assistance in interpreting the social and political life of the past, and for similar reasons it welcomes the advance of any new sciences, such as comparative and social psychology, which promise to throw further light upon the social life of man.

Unlike the natural sciences, history cannot avail itself of experiment or of repeated observation. Except for the infinitely small body of information which has been acquired by his immediate personal experience, the historian depends entirely upon indirect sources of knowledge, arriving at the facts of the past only by working back from the existing traces which they have left behind them. These traces, the fountainhead of historical knowledge, are called sources. Originally limited to the oral traditions handed down in song and story, and then including written material in the bare lists of early inscriptions and annals, the conception of what constitutes an historical source has widened with the growth of knowledge and with the enlargement of our ideas of the scope of history until it now includes, not only chronicles and public documents, but newspapers and private correspondence, buildings and pictures, ideas, customs, and superstitions, clothing and tools and implements and every sort of object from which information respecting the human past may be derived. For purposes of convenience, sources are often classified into narrative, such as biographies, chronicles, and memoirs; documentary, including laws, charters, and official acts of every sort; literary, so

far as literature throws light on the ideas and conditions of an age; and archæological, including the great body of monuments, works of art, and material remains. The use of these materials for historical purposes often demands technical knowledge of a very special sort, and a group of subjects has grown up which are often called the "auxiliary sciences" of history. Chief among these are language, as a means to the understanding of historical records; palæography, or the science of ancient writings; diplomatics, treating of official documents; epigraphy, or the science of inscriptions; numismatics, archæology, chronology, and historical geography.

Out of such materials and with such aids, it is the business of the historian to reconstruct the past for his readers. After he has collected his sources by patient research in libraries, archives, museums, and similar repositories, he cannot use them until he has subjected them to a searching critical examination with reference to their origin, genuineness, credibility, and value. In the case of narrative and documentary sources this may involve elaborate textual criticism in order to restore the original form of a document, the determination by external and internal evidence of its authorship and the time and circumstances of its composition (the so-called "higher criticism"), and the weighing of the value of the various assertions which the document contains, with reference to the knowledge, good faith, and impartiality of the author. The chances of error in the transmission of evidence are great, and they are enormously increased by the fact that in the case of all written or spoken sources we can only arrive at the original fact through the intermediary of the human mind which transmitted its subjective impression to us, so that history is often reproached with the uncertainty which may exist regarding events of the highest importance. While this human element makes it impossible for historical knowledge ever to attain the degree of precision and certainty which belongs to the sciences of observation, the historian is able, by means of converging lines of evidence, to establish such moral certainty as may be reached in the affairs of men; and, although this assurance is often lacking respecting particular events of a remote period, it becomes sufficient for any purpose in the case of ideas, institutions, and social conditions of wide prevalence or continued duration. Regarded from this point of view, the thoroughness of its critical search for truth and the nature of its results entitle history to rank as a science. On the other hand, the processes of historical synthesis by which the historian combines individual facts into sequences and generalizations, and with the aid of the constructive imagination groups them into an ordered work of history, give a much greater opportunity for variation and individual choice, and on this

side of historical method there is as yet no such general agreement as has been reached respecting the analytic operations of historical criticism. Moreover, the form in which the result of the historian's labors are presented to the reader is a question of art, more important here than in the case of the natural sciences because of the element of sympathy and imagination which arises out of the human appeal of the subject matter of history, and the artistic presentation of history is thus a branch of literature. Inasmuch as the critical faculty, the constructive imagination, and high literary art are seldom combined in the same person, it rarely happens that a work is produced which is eminent both as a work of historical science and as a work of literature. This tends to a division of labor by which the preliminary operations of collection, criticism, and arrangement are performed by the editors of texts, the authors of *regesta*, and the writers of monographs, leaving to the synthetic historian the more ambitious tasks of historical construction. Such a division can, however, never become complete, for the historian must know how to test for himself the materials with which he is to build, and both the writer and the teacher of history must understand, though they need not regularly use, the whole historical process.

The teaching of history, at least in the higher grades of instruction, is concerned with a body of knowledge, a point of view, and a method of inquiry. The body of historical knowledge is enormous and is constantly enlarged by the progress of historical investigation as well as by the lapse of time, and the problem of the teacher is, in the first instance, to select those facts which will make clear the general course of historical development and contribute to an understanding of the periods and countries of special significance with reference to the world as a whole and to the particular country and age in which the student lives. These facts must on the one hand be seen as actual realities, against their contemporary background, while on the other hand they must be grasped, not as disconnected events or dates, but as bound together in certain relations and forming part of a continuous process of development. The student must learn that while the past is vitally connected with the present and can only be reconstructed by working back from the phenomena of actual experience, it was never the same as the present, and he must be taught to lay aside for the moment the ideas and standards of his own age in order to enter into those of the age he is studying. Impartiality, sympathy, and imagination thus become necessary qualifications for the study and teaching of history, and the attitude toward the past which is thus attained is often called "historical-mindedness." One element in this is the critical spirit, and the general student of history finds it necessary to know something of the way the historian collects

and tests his materials, while the special student requires initiation into the nature of historical evidence and the processes of historical criticism and construction. Such training is necessary, not only for the professed historian, but also for those who as investigators of topics in economics, political science, education, and the history of literature, art, or philosophy, are, often without realizing it, obliged to make use of the historical method of inquiry. In the earlier stages of historical instruction, attention is given particularly to the teaching of a few simple facts and the development of the historical imagination; in the higher stages the number of facts increases and more emphasis is put upon their relations and political and social significance, and upon the acquisition of a critical and impartial habit of mind; while in the most advanced grades of instruction the student learns to find, test, and combine his facts for himself until he is able to undertake independent research.

Probably no other subject of study is so dependent upon great libraries as history. The sciences of observation depend primarily upon field work or the laboratory; the specialist in literature or philosophy can go far with a small collection of the great works in his department, but the student of history not only needs the newest works upon his subject and the standard authorities whose views he must compare and examine, but he is constantly driven back to the sources of information, which in history are almost endless. For him no book is or can ever be wholly "dead," since when it ceases to have value as a statement of facts, it always retains a place in the history of learning or of ideas, and thus serves as a source of historical knowledge. The efficiency of a university department of history is closely conditioned by the libraries to which it has access, and these must be rich in the great collections of printed chronicles and documents and in the files of periodicals and publications of learned societies, as well as in current historical treatises. Moreover, as no single library can hope to be complete, even for printed works, advanced investigation involves the necessity of visiting other libraries and archives for rare and unpublished material. For many fields of history, as well as for the whole period before written records begin, museums of art and archaeology perform a function analogous to the library as repositories of historical materials, and access to them may in many cases be equally indispensable.

**History in European Universities** — Although history is as old as the Greeks, it has acquired academic status only in comparatively recent times. The curriculum of the medieval universities made no provision for history, as it made none for literature, nor did the revival of learning prove immediately favorable to historical study. The only period of history

for which the humanists cared was the Græco-Roman, and the study of history remained a subordinate part of the study of the Greek and Latin classics, just as oriental history was limited to a study of the Old Testament. The Protestant Revolt and the Catholic reaction gave an impetus to the study of the Middle Ages, but only on the ecclesiastical side, and so far as these movements furthered the teaching of history in universities and seminaries, their influence was confined to the history of the Christian church. The separation of history from philology on the one hand and from theology on the other was slowly accomplished and is not yet at all points complete. As an independent subject history gained its footing gradually in the course of the eighteenth century and became fully established only in the nineteenth. The rapid expansion of historical instruction in the course of the past hundred years has come about partly as the result of the great activity of historical research and the enormous extension of historical knowledge in this period, partly through the growth of nationality and democracy, and the consequent efforts to cultivate patriotism and develop the civic virtues, and partly from a realization of the need of giving the youth of each generation an orientation with reference to the development of the world's civilization and their own place in it.

In the universities of Germany history acquired an independent status in the eighteenth century, notably at the University of Göttingen, but German historical scholarship showed no peculiar strength in this period, and its preeminence was established by the school of writers and teachers which had its center in Berlin between 1810 and 1830. The pioneer in this movement was Niebuhr, in the lectures on Roman history which he gave as professor at the University of Berlin and which formed the basis of his writings on this subject, and his influence was soon apparent in the spread of his critical methods to other fields of history and in the application of the historical habit of thought to the study of law, language, and religion. With Niebuhr, as with German professors since his time, the writing and teaching of history went hand in hand, and the connection became still closer through the methods of teaching introduced in 1825 by Leopold von Ranke. "Ranke," says Lord Acton, "has not only written a larger number of mostly excellent books than any other man that ever lived, but he has taken pains from the first to explain how the thing is done." His first book, written in 1824, was accompanied by a critical discussion of the materials upon which it was based, and in the following year he reinforced his lectures at the University of Berlin by the inauguration of an historical seminary. The idea of such a meeting of professors and students for training and practice in the critical use of historical sources Ranke borrowed from

the classical seminaries of which he had been a member at Göttingen; but it soon became an established feature of the university system, and in one form or another (seminary, practical exercises, *cours pratique*) it is now generally recognized as an essential element in higher historical instruction. The purpose of the historical seminary is to teach not the facts of history, but the process of historical investigation, and it is designed as a part of the training of the teacher as well as of the investigator. "An essential characteristic of the work," as it has recently been analyzed by Professor George B. Adams, is the practice of the methods of historical criticism and synthesis "together by a number of students of about the same stage of advancement, and the resulting mutual criticism and stimulus of mind by mind." The group of students must necessarily be small, and the relations with the instructor must be free and informal. The subject of study may consist of a chronicle, a series of documents, or a limited historical period or movement, and the work may be conducted either by joint discussion of a topic prepared by all the members of the seminary or through the presentation and criticism of reports or essays assigned to individual members; but such work cannot profitably be carried on unless it is so arranged that all members may take an intelligent part. The method is essentially cooperative, and frequently results in a group of published studies upon related topics. The narrative lecture and the seminary constitute the regular forms of historical teaching in the universities of Germany, Austria, and German Switzerland, and practically all these institutions maintain such instruction in ancient, in medieval, and in modern history, while at a university such as Berlin a great variety of seminary and lecture courses is offered. Significant types of allied institutions are the *Institut für österreichische Geschichtsforschung* at Vienna, which gives a thorough grounding in the auxiliary sciences and in other subjects necessary for the study of Austrian history, and the *Institut für Universalgeschichte* at Leipzig, where Professor Lamprecht has led a revolt against the more strictly political form of history cultivated by the followers of Ranke.

In France a chair of history was established at the Collège de France in 1769, but although the incumbents comprised men of the distinction of Guizot (*qv*) and Michelet, they tended to address their lectures to the general public rather than to students and had no special functions as teachers. The professorships at the Sorbonne were of the same sort, so that until the close of the Second Empire the actual teaching of history at Paris was confined to the *École Normale Supérieure*, which prepared teachers for the *lycées* and colleges, and the *École des Chartes*, established in 1821 for the training of archivists and librarians, but developing an excellent set of special courses

which gave a sound historical training, especially in the medieval field. The foundation of the *École des Hautes Études* in 1868 opened opportunities for the special study of history similar to those afforded by the German seminary, and under the Third Republic the strengthening of the faculties of letters and the development of a university organization have given a large place to historical instruction. The universities now perform the functions once monopolized by the *École Normale*, which is now combined with the University of Paris, and in addition to the public lecture courses maintain *cours fermés* for the special training of teachers and scholars in the principal fields of history. The change in the character of university instruction is seen in the modification of the requirements of the *agrégation d'histoire*, the competitive selection of professors of history in the *lycées*, which in addition to the comprehensive examination on the general field of history now demands a thesis based upon original sources, and certain examinations on more special topics. The provincial universities seek, so far as their resources permit, to do the same kind of work as the University of Paris, but they are less liberally supported than the corresponding German institutions, and their students of history are at a special disadvantage because of the absence of the special schools and great libraries of the capital. Besides the more strictly academic training of the *École des Chartes* and the *École des Hautes Études*, the *École Libre des Sciences Politiques*, a private institution established in 1871 primarily for the purpose of fitting young men for the civil service, offers instruction in modern political and diplomatic history.

The Camden Professorship of Ancient History was founded at Oxford in 1622, and the Regius professorships of Modern History at Oxford and Cambridge in 1724, but it was not until the second half of the nineteenth century that historical studies began to occupy a position of importance in the English universities. Long subordinated to classics and later to law and the moral sciences, history was given an independent status through the establishment of the Honori School of Modern History at Oxford in 1872 and the Historical Tripos at Cambridge in 1875. The historical instruction thus organized has been almost entirely directed to the preparation of undergraduates for the final examinations for their degrees, and to this end emphasis is laid upon wide and thorough reading in standard authorities under the guidance of a tutor, who is responsible for but a small number of students. Brief courses of lectures are also given by the tutors and lecturers of the various colleges on the principal periods and fields of history covered by the examinations. Recently some progress has been made in the direction of advanced teaching, especially on the part of the university professors, who take no part in preparing under-

graduates for examinations and thus have considerable leisure for graduate instruction and the guidance of research. So far few English students have availed themselves of the privileges of this sort of study, but the research degree of B Litt., recently established at Oxford, has proved attractive to a certain number of graduates of American and colonial colleges. Among the newer English universities the University of Manchester is an important center of historical study, and the University of Liverpool has recently organized a special school of local history and records.

**History in American Colleges** — Like their English contemporaries, the early American colleges made no regular provision for the study of history. The curriculum was predominantly classical, and historical instruction was limited to the history and antiquities of Greece and Rome. In course of time a few recitations upon a manual of universal history were introduced, but the nature of the required curriculum gave no opportunity for the growth of organized historical instruction. A professor of ecclesiastical history was appointed at Yale College in 1778, but the first professorship of history in the more general sense of the term was created at Harvard in 1839, and filled by Jared Sparks, who three years later brought the study of American history for the first time into an American college. Another significant date is 1857, when Henry W. Torrey took up at Harvard the work which Sparks had relinquished when he resigned the presidency in 1853, and when Francis Lieber became professor at Columbia and Andrew D. White at the University of Michigan. These three men had been trained in Germany, and the development of historical studies in the United States during the next twenty-five years is directly traceable to the influence of the German historical school. This movement, however, began slowly, and outside of the three institutions just named the systematic teaching of history belongs to the period since the Civil War. Some qualification of this statement is necessary as regards the colleges of the South, where in the generation preceding the war historical and political studies received more attention than in the North; for example, Lieber had been professor in the University of South Carolina, and instruction in history and political science, though not provided for by special chairs, had an important place in Jefferson's plans for the University of Virginia. Even in the more recent period history has made way more slowly in the smaller colleges of the East than in the state universities of the West, where the traditional subjects of the curriculum have had a weaker hold; but at the present time every reputable college has at least one professor of history and a regular sequence of historical courses which offer some sort of view of the history of the world in general and of the United States in particular.

The organization of the historical curriculum in American colleges is conditioned by the fact that their freshmen have reached the age of students in European universities without having acquired any such accurate and substantial knowledge of historical facts as is possessed by pupils of the corresponding stage of the gymnasium or the *lycée*. Accordingly, while it is possible in the later years of the college course to do work which is in many respects of university quality, this work suffers from the lack of a sufficient basis of knowledge and discipline, while the earlier years of the course must be devoted in large part to carrying on studies of secondary grade with students who are too old for the methods of secondary instruction. For this reason it is particularly important that the teaching of history should begin with the freshman year, in order to remedy as soon as possible the defects of the students' earlier training. The problem of the introductory course in college is, however, peculiarly difficult, since this course is likely to be taken by a large number of students, of wide diversity of preparation and interests, and since it has not only to serve as a basis for more advanced work, but also to meet the needs of those whose formal study of history will stop at this point. The effort must here be made to give at the same time a body of definite historical information, some training in the use of historical material, and some quickening of the imagination and broadening of the historical horizon. The field chosen must be large enough to give an idea of the growth of institutions and the character of historical development, yet not so extensive as to render impossible an acquaintance at close range with the men and conditions of the times; but it cannot be said that any general agreement has yet been reached as to the course which best fulfills these conditions. With rare exceptions, of which Columbia College and the University of California are the most notable, the attempt is no longer made to cover the whole range of universal history in the first course in college, as so rapid a survey has generally proved confusing and unsatisfactory; a favorite type of course is one covering the history of Europe from the close of the Roman period to the eighteenth century or, more commonly, to the close of the nineteenth. Some colleges, such as Harvard, Wisconsin, and Kansas, finding this period too long, limit the introductory course to the Middle Ages, in order to secure time for more thorough study and more careful training. In some instances, a general course in English history is given for this purpose; at other places a course in ancient history; while Cornell, Wisconsin, Pennsylvania, and some others offer two or more parallel courses for beginners, an arrangement which avoids some difficulties but loses the advantage of uniform preparation for later courses and tends to keep students too long in the ele-

mentary stage American history is generally regarded as not well suited for this purpose, since it is commonly studied in the last year of the high school and does not offer the freshness of interest and the breadth of view desirable at the beginning of college work.

An introductory course of this kind should be taken by all college students, and most of them should be encouraged to take two or three additional courses as an essential part of their general education. For the needs of the general student every college should provide instruction in ancient history, the history of the Middle Ages and of modern Europe, English history, and American history. How far courses in these fields should be multiplied and subdivided is a matter which each institution must decide for itself, provided always that it remains possible for the ordinary undergraduate to get a fairly satisfactory survey of the general field of history without devoting an unreasonable amount of time to the subject. Some subdivision is desirable in every institution in order that students may have opportunity for the more intensive study of a period or topic, as a means to the fuller comprehension of what history is and how it is studied. It is also important that toward the close of their college work students of special aptitude for history should have access to an elementary seminary or practice course, not only for historical training and for an understanding of the subject chosen, but also as a step toward the intellectual independence which comes from forming one's own conclusions after a careful examination of all available evidence. If the topic for such a course is not beyond the powers of a good senior, its selection may well be determined by the facilities of the library and the special interest and competence of the instructor. In all questions of the historical curriculum there is great diversity of practice among American colleges, and while there is a growing tendency to pay attention to the experience of other institutions, uniformity is neither desirable nor at present attainable. Moreover, the field of history is so vast and its variety so great that it will never be possible to establish any such regularity and definiteness of order as exists in the case of courses in mathematics and natural science.

With respect to the methods of college instruction, equal diversity exists. The slavish memorizing of textbooks, once practically universal, has generally been abandoned, and the text is now supplemented or replaced by lectures, prescribed or recommended reading, and written reports, often reinforced by an outline or syllabus. Illustrative material of various kinds has been introduced, and the outline map has proved a valuable adjunct for the teaching of historical geography. Considerable use is now made of extracts from the sources in undergraduate instruction, partly for greater vividness and freshness, partly, as

in the case of constitutional documents, as a means to the more thorough understanding of significant topics, and partly for exercises in the process of historical criticism and construction. The systematic use of such material at all stages of college work has been especially notable at the University of Nebraska. As a result of these changes, the textbook itself has been greatly improved in the past twenty-five years, although, for commercial reasons, school and college texts in history are as yet imperfectly differentiated.

One of the most difficult problems in the college teaching of history is that of the management of the large classes, numbering from fifty to five hundred, which have developed in all but the smallest of American colleges and for which the teachers of history and similar subjects can hardly be said to have worked out a method equal to the laboratory work which accompanies classes of this size in the field of natural science. Many colleges have adopted the so-called "Harvard system," by which the class meets together for lectures and is divided into small sections under instructors and assistants for discussion and quiz upon the lectures and the assigned reading. This method is most effective when a written test forms part of the work of the sections and when frequent individual conferences are also held. It is the most economical system and the only one which brings all members of the class into contact with the most experienced teachers in the department, but it requires for its success a larger number of thoroughly competent assistants than is usually available. Elsewhere, as at Yale, Columbia, and Chicago, the class meets only in sections, an arrangement which provides well for daily drill but cuts off a considerable body of students from any contact with men of professorial rank, as no college has yet been willing to furnish a staff of highly paid men sufficient to conduct all the divisions of so large a class. At Princeton and Bowdoin the method first described has been modified and carried much farther by means of preceptors who direct the students' reading in groups of four or five, an exceedingly costly arrangement which shows promise but has not yet been tested on a large scale with introductory courses.

#### The University Study of History in America.

— The university study of history in the United States may be said to have begun with the original investigations in medieval institutions which were undertaken at Harvard University in 1874 by a group of advanced students under the direction of Henry Adams and which bore fruit in 1876 in a volume entitled *Essays in Anglo-Saxon Law*. An "historical seminary" for seniors had, it is true, been organized at the University of Michigan by Charles Kendall Adams (*qv*) in 1869, but it was of a general and elementary character and did not reach an advanced stage till ten years later. Seminary

work in history was likewise a feature of the system of graduate study instituted by the Johns Hopkins University at its foundation in 1876, and after 1881, under the leadership of Herbert Baxter Adams (*q v*), this seminary exerted a wide and fruitful influence upon the study of American institutions and upon methods of teaching throughout the country. In 1880 Columbia University organized a Faculty of Political Science, in which the study of constitutional and legal history held an important place, and about the same time more adequate provision for advanced instruction in history was made at Cornell University, where the first distinct professorship of American history in the United States was established in 1881.

While the introduction of the seminary method was the determining element in the differentiation of the higher study of history in America, the line between college and university work has never been sharply drawn in this subject, nor is such demarcation likely in the near future, since it is possible to begin certain kinds of original investigation in college, while on the other hand the preparation of the advanced student and teacher demands a large amount of general work which cannot be completed in college and can best be carried on in the graduate school along with the beginnings of independent investigation. Accordingly under American conditions the transition from elementary to advanced work in history is more gradual than in European universities, while at the same time the antithesis between the lecture and the seminary methods of teaching is less strictly observed, many of the most profitable graduate courses being conducted by a combination of lectures, student reports, and class discussions. Free use is everywhere made of the library, indeed the freedom of access to the stack and the greater promptness of service in American libraries are points of distinct superiority over European institutions of learning; but at most American universities the resources of the library, outside of narrowly limited fields, are quite inadequate for the most advanced historical work. Another characteristic of the advanced study of history in America is the close connection maintained with economics and political science, both in the organization of instruction and in the emphasis put upon the economic and constitutional aspects of history, and subjects like economic and diplomatic history are often left to these related departments.

A well organized university department of history needs a great library and the support of strong departments in related fields; it must also offer advanced instruction in ancient, mediæval, and modern history, as well as in such fields as economic history, ecclesiastical history, and the history of religion, and in the auxiliary sciences. Special attention will naturally be paid to the history of the United

States and of those countries and movements most closely connected with American history. At present the universities which have the most extensive equipment of teachers and books in these various fields are Harvard, Yale, and Columbia, each with a dozen professors and assistant professors of history. Well developed graduate departments of history are also maintained by Chicago, Cornell, Pennsylvania, and Wisconsin. Illinois and Michigan also have important departments, while at Johns Hopkins and Bryn Mawr graduate work in history is definitely organized, but with a smaller body of teachers. Certain other universities do graduate work of good quality in more limited fields, notably the University of California on the history of the Pacific Coast and the University of Nebraska on the French Revolution, and most of the state universities carry candidates as far as the master's degree, if not farther. The state universities regularly omit any special treatment of church history and the history of religions. Topics which have recently obtained a footing in historical departments are the history of Latin America, which receives particular attention at Columbia, Yale, Illinois, and California, and modern Oriental history, represented most fully at Yale and to a less degree at Wisconsin, Columbia, and Harvard. Proper university provision for the promotion of research also demands the creation of traveling fellowships, for the exploration of libraries and archives at a distance, and opportunities for publishing the results of the investigations of professors and advanced students. So far Harvard is the only university which possesses regularly endowed traveling fellowships in history, but several institutions have established organs of monographic publication. The most important special series are the *Johns Hopkins University Studies in History and Political Science* (since 1882); the *Columbia Studies in History, Economics, and Public Law* (1891); the *Bulletins of the University of Wisconsin* (1894), with an Historical Series and an Economic and Political Science Series, and the *Harvard Historical Studies* (1896) and *Harvard Economic Studies* (1906). At several other universities facilities exist for the publication of historical monographs, either as members of a general series of university studies, or in conjunction with the work of state departments of history or local historical societies. The majority of such products of seminary study naturally relate to topics of American history, but excellent monographs are also produced in various fields of European, and especially of English, history. C. H. H.

**History in the Secondary and Elementary Schools.**—The teaching of history in the secondary or elementary schools presents two main problems: first, the relative amount of time which should be assigned to the subject,

with the periods or kinds of history to which this time should be given; second, the methods of instruction. Each of these problems must be examined separately for the secondary and for the elementary school. History is a record of human experience, the rich variety of which is not indiscriminately valuable for children of all ages. The effort to find answers to these questions of matter and method appears late in the development of educational systems. This is mainly due to the fact that not until the nineteenth century was the study of history well organized in the universities.

Before the *Report of the Committee of Ten*, made in 1892, the work of the secondary schools in history was usually composed of courses in Greek and Roman history for pupils looking forward to college studies, with a brief course in English or "general" history for others. The schools with a more developed program were so rare that their practice is not significant. For the year 1889-1890 only 27 per cent of the pupils in the public secondary schools were studying history. In the elementary schools American history was generally taught in the seventh and eighth grades alone. As the majority of the pupils did not remain in school until the seventh grade was reached, they received practically no instruction in history. The subject had long been gaining more intelligent attention in France and Germany. With the organization of the *lycée* and the *gymnasium* early in the nineteenth century it was given an important place on the program of the secondary school. The recognition of its value for elementary education came later. In England, until Arnold's time, there was little systematic teaching of history in the "public" schools, and even after his day, except at Rugby and Harrow, the character of the work depended upon the interest of the individual teacher.

The *Report of the Committee of Ten* (qv) of the National Education Association, embodying the results of the Madison Conference, brought the question forward and suggested a program covering the last four years of the elementary school as well as the four years of the secondary school. The most important single influence in the movement toward the adoption of a standard program for secondary schools has been the *Report of the Committee of Seven*, of the American Historical Association, which appeared in 1899. This recommended a four years' course, beginning with ancient history in the first year, placing medieval and modern history in the second, English in the third, and closing with American history and civics in the fourth year. Effect was given to the recommendations of the committee by the action of the prominent textbook publishers in arranging for series of texts constructed according to the plan. Another influence has been the requirements fixed by colleges for entrance either upon examination

or by certificate. (See COLLEGE REQUIREMENTS FOR ADMISSION.) The complete success of the movement for uniformity has been hindered by the consequences of the elective system introduced into the schools. Sometimes also the fact that many colleges have not given credit for more than one or two units of history had a similarly retarding influence. An investigation made in 1909, principally of schools in the Middle West, showed, however, that out of eighty-three schools offering a three years' course fifty-six required all three units for graduation.

Dissent from the recommendations of the Committee of Seven has usually been prompted by the desire to lay greater emphasis upon the modern period. In order to satisfy this desire a Committee of Five, partly of the same personnel, also appointed by the American Historical Association, advised that schools ready to make a change should place English history as far as 1760, with its European connections, in the second year and give the third year to a course on the last century and a half of European history.

The recent development of commercial and technical high schools has rendered necessary a course adapted to their requirements. For them emphasis should be put upon the history of the arts and of trade. The interests of the two are also distinct, because, although the achievements of the Greeks and the Romans, and, in a measure, of medieval peoples, are instructive to students of certain technical arts, students of commerce will find the modern period the most important. Both should be taught to place the special aspects of life which they study in a true historical setting, while at the same time they should not forget other phases of history which explain the general growth of civilization.

The attempt to construct a standard course for the elementary schools has been beset with even greater difficulties, because many diverse authorities must be brought into harmony, and because of excessive assignments of time to other studies, especially geography. Typical solutions of the problem have recently been presented by the University of the State of New York in a *Syllabus*, by the teachers of the Horace Mann School in their *Elementary School Curriculum*, by the Chicago University Elementary School, by the Indiana State Board of Education, and by the Committee of Eight of the American Historical Association.

The New York *Syllabus* divides American history into two cycles, the first, principally in a series of biographies, occupying the fifth and the sixth years, the second, with a narrative treatment, occupying the seventh and eighth years. The plan adopted in the Chicago University Elementary School is the most radical departure from traditional arrangements of program, and is based on the attempt to develop the pupil's historical sense in con-

nection with his own industrial activities or those of the community in which he lives, and without much attention to chronological sequence. The curriculum suggested by teachers of the Horace Mann School, after providing stories and exercises drawn from primitive life for the youngest children, begins at the third grade with work on the Phœnicians, as typical of ancient trade and adventure, and passes by a natural transition to the stories of Columbus and of Hudson, and to the early history of Manhattan. In the fourth grade there is a study of the typical men of America, closely correlated with the study of geography. This is followed in the fifth grade by Greek and Roman history, and in the sixth by medieval history, passing over into the work of the discoverers and colonizers, in order to show the movement out of which America grew and to emphasize the fact that American civilization did not have its beginnings in the first settlements. In the seventh grade, which is the final grade, there is a study of American history from the struggle between the French and the English for control in America to the present day. The program of the Indiana State Board of Education offers certain similarities to this course, although it gives only part of one grade to stories of primitive life, follows these by stories of American heroes, emphasizes the heroes of Hebrew history as well as those of Greece and Rome, and gives the sixth year to English history, followed by two years of American history and civics (*qv*).

The plan of the Committee of Eight was based on the conviction, shared with the framers of the courses already described, that in teaching American history too little account had been taken of the European background or of the origin in Europe of American civilization. The plan falls into two parts, the first suggesting simple tales and descriptions of types of life easily intelligible to children of the three earlier grades, developing into a biographical treatment of American history in grades four and five. In the second part is outlined a course, continuous chronologically, for grades six, seven, and eight. Two thirds of the time of the sixth grade is given to what may be called an elementary introduction to the study of American history. Its topics include typical characters, stories, ways of living, selected from the most characteristic periods, beginning with the age of the Greeks and closing with the age of Columbus. In the later portions of the course stories and descriptions from the European background are introduced wherever this makes the setting of American history more intelligible.

In France and Germany the secondary school, *lycée* or *gymnasium*, gives instruction in history throughout a nine years' course. The course corresponds to a possible course in our schools running from the fifth grade through the elementary school, the secondary school, and up to the third college year. History is also given

in elementary schools distinct from the *lycée* and the *gymnasium*, and is parallel, therefore, to the first part of the secondary school course. In the elementary school the content is confined more exclusively to the national history and omits ancient history. The last seven years of the secondary course are divided into two cycles, one of four and one of three years, thus including two journeys through the field from ancient times to the present day. In the second cycle of the French course, if the pupil is on the classical side, *ie* has Latin and Greek, or Latin and the "living" languages, he devotes four hours to history, two to ancient and two to modern, if he takes the sciences with either Latin or the living languages, he devotes two hours to modern history. Except at this period of the course, the time given to history, both in German and French schools, averages three hours a week and the work is correlated closely with geography.

In England the average amount of time given to the subject is two hours a week in both the preparatory years and in the secondary school proper. On account of the variety of type in the organization of the English schools it is difficult to summarize the practice. The most authoritative recommendation is presented in Circular 599, published by the Board of Education in 1908, and includes, for the first stage, with children up to the age of twelve, stories from the history of England and of other countries, centering about great characters like Charlemagne, Columbus, and Washington, as well as famous Englishmen; for the ages between twelve and sixteen, a chronologically continuous course in English history with the European connections, during the final years, classical history for students going to the universities, for others English or modern continental history. The Circular records the gradual falling off in the practice of introducing a special period for more intensive study, and argues that there should be judicious selection all the way through of incidents and characters for special emphasis. The Circular also criticizes the concentric method by which in some schools the whole subject of English history is gone over each year summarily. In too many instances history is lumped in the program with "English subjects." The general influence of the type of questions asked in various public examinations, in competition for prizes, honors, etc., has been to retard the development of a plan of study satisfactory to the more progressive teachers.

From the practice abroad, as well as from the character of the efforts to promote the teaching of history in American schools, it is evident that the best opinion is in agreement upon the necessity of making the instruction continuous throughout the pupil's school career. Only by this means is it possible to form in his mind a useful framework of historical events and to train him to think of events historically.

Time is also needed for the growth of interest and the formation of a habit of reading historical books. In the opinion of a recent French minister of public instruction the habit of reading historical books is an important element of the reading habit, which, next to the habit of observation, should be the aim of popular education, and without which the pupils are in danger of falling into illiteracy after they leave school.

**Methods of Teaching** — Upon methods of teaching there is less agreement than upon questions of program, although for the attainment of the aims of the subject an effective method is more important than the choice of any particular period for study. If the method of teaching is not effective, the subject is discredited as an instrument of education. As the matter now stands, the statement that a pupil has had a course in ancient or medieval and modern history, means much, little, or worse than nothing. The most urgent need of the present time is the adoption and the general practice of a well-considered method of teaching the subject. In the management of subjects which are already well organized pedagogically, like English, chemistry, or Latin, teachers know what is expected the first month, the first term, the first year, they realize what are regarded as the essential elements of a good method. But the teacher of history may confine his work wholly to the explanation of the paragraphs of the textbook, or he may assign selections for reading in other books, or he may also utilize collections of source material. He may tram his pupils in the use of notebooks or he may never allude to them. What he shall decide to do seems to depend generally upon his individual preference. The well-trained teacher is capable of solving the problem for himself, but many others are groping about among haphazard experiments or apathetically following methods sanctioned by local tradition.

In Germany there is a recognized method of teaching history. This is true of France also, although French teachers differ among themselves in regard to the function of the textbook. In Germany reliance is placed mainly on the teacher and the instruction is principally oral. Many teachers even object to the use of a notebook during a class exercise, because they wish the attention of the pupils concentrated upon what they are saying. By a process of questioning and repetition they work the facts literally into the pupil's mind, so that he is gradually enabled to construct so solid a framework of the past that it is serviceable for all his future work whether in the university or elsewhere. Books of simple outlines, or *Leitfaden*, are used to supplement the oral work. So complete is the dependence upon the teacher that few or no references are given to historical works and there is slight use of selected sources. This has been criticized as not offering the pupil

enough training for independent work in history and as being in one respect a poor preparation for the freedom of university work. Such reliance upon the teacher is possible only because of the thorough training insisted upon by the State in the case of every teacher. In both France and Germany the subject is intrusted almost wholly to special teachers. Although the French use the textbook more than the Germans, they generally go over the lesson in a carefully prepared lecture which the pupils record in notebooks. The reason for this when a textbook is also used, is the need of placing the right emphasis and of stimulating the attention. It is believed that by such a method the dull pupil obtains more than if he is expected to master without direction the topics assigned. The French do not make extensive use of selected sources or of other reading references. In England, with no central controlling authority, the methods of work show less uniformity than those of France or Germany, but where the subject is well taught it is likely to include excellent training in writing up topics on the basis of an intelligent use of reading references.

European methods of teaching history should not be transferred mechanically to American practice, but acquaintance with them emphasizes the value of a standard of work and directs attention to the elements of the problem. What may be suited admirably to the needs of the German boy in the *gymnasium* or the French boy in the *lycée* may not take sufficient account of the more precocious individuality of the American boy. An adequate method must be the outcome of a careful study of the child and a wise consideration of the benefits which he should derive from his work in history. The study of history should give him not merely a body of information, it should affect his attitude towards the world and tram his mind for the successful search for certain kinds of truth.

In the elementary school the question of method, like the question of program, is partly conditioned by the fact that many pupils leave school at the end of the fifth grade. For such a pupil the most that can be hoped is some acquaintance with the history of the United States through stories, primarily biographical, and pictures of life and customs. Stories of the great world heroes should be added. At this stage it is upon the never-failing interest of the story well told that the main reliance must be placed. The teacher should be trained for his work as the librarians of children's libraries are trained for the "story hour." The most usual defect of the story is its lack of vivifying details, which enable the comparatively feeble imaginative power of the child to form a picture of the incident as of something that actually happened. Children of the fourth and fifth grades are also beginning to read for themselves, and they should be led to read stories from history. It is unnecessary

to emphasize the need of correlating this work with what is done in English and in geography.

In the higher grades of the elementary school the pupil should be enabled to form a picture, fairly accurate in its details, and in chronological order, of the principal events of American history and of its European background, in order that it may be a serviceable framework for later historical knowledge. More emphasis should be laid upon reading, in books furnished by the school library or by local public libraries. Some use can also be made of original sources, with the aim of illustrating facts easily within the comprehension of children of this age. Selections which illustrate two sides of a controversy, like that between Parliament and the colonies after 1765, or between the North and the South before the Civil War, will train pupils, who are beginning to read the newspapers, to read more intelligently and with some effort of judgment. There should be practice in making simple maps, explaining geographically an historical situation. Outline maps may be used for this work. Pictures offer an opportunity not only for awakening interest, but also for giving training in observation.

The problem of method for the secondary school is more complex, because the element of training should receive greater emphasis. The most obvious requirement of a course is the mastery of the contents of the textbook. To attain this result there are needed, besides the ordinary recitation exercises, the preparation of outlines and summaries, the construction of what the English call "date strips," and the preparation of reviews. The teachers most interested in the improvement of the teaching of history would add some reading from historical books other than the textbook, the study of selected sources of a simple and clearly illustrative character, and the making of reports upon topics with the use of several books of reference. There must also be the construction of maps. How many of these exercises the individual teacher may be able to embody in any particular course depends upon the special conditions of the school, that is, the amount of other work demanded of the teacher, the existence of a school or public library, the number of available historical maps, etc. Each exercise should be repeated at least once, because the first attempt serves principally to make clear the difficulties. There should be orderly progress in the manner of work from the beginning to the end of the course. The pupil is studying history in order to learn how to study history as well as to acquire a body of historical facts. Each exercise should have relation to its predecessor and to what is to follow.

The teacher's first task should be to construct a calendar of the course, apportioning the work of each day, and indicating at what stage any particular exercise is to be attempted. An examination of the textbook will show what

topics are adequately treated and upon what topics there must be supplementary oral explanations or informal lectures. It is apparent that an exercise in constructing summaries should be inserted after an epoch of marked characteristics has been studied. Upon the completion of the study of a long and complex process an outline, chronological or topical, will be useful. Teachers may wish to use a simple outline for each day's work, but the construction of such outlines should not be required every day of all the class, for this work would soon become mechanical and wearisome. A review of the geographical relations of the subject will show at what points illustrative maps should be constructed. Certain topics should be studied partly through the medium of pictures. (See VISUAL AIDS TO TEACHING.) If there are to be reports on long readings, the place of these will be determined by the interest of the topic or incident and the availability of books on the subject. The same is true of topical studies, of which there should not be more than two or three during the particular course. The results of these exercises should be embodied in the pupil's notebook. They should be written on sheets of paper which may be inserted without copying in a loose-leaf notebook. The pupil will need careful instruction upon the manner of preparing this written material for the notebook.

The teacher may not be able to insert upon the calendar more than an indispensable minimum of exercises, because such exercises require efficient supervision, and the burden upon the average teacher is already heavy. The way to meet the difficulties of the situation is to agree upon what this indispensable minimum includes, and from it as a basis work steadily toward the desirable. H E B

### HISTORY OF EDUCATION — Its Value

— An appreciation of the value of the study of educational traditions and customs is united with the tardy recognition of culture history in general. The earlier study of historic aspects of education was connected either with particular institutions, chiefly universities, or with the philosophical interpretation of education. Recently, however, a wider significance is recognized both because of the function of the study in professional education and of its cultural value. Certain of these reasons may be indicated briefly. In the first place the recent strong emphasis upon the genetic approach has brought into clearer light the significance of the historical, if a large proportion of our educational ideas and practices have no other support in the present but a historical or traditional one, it is quite essential to the teacher to know something of the origin and significance of these customs. Again as a guard against the danger of extremes in moving away from the restrictions of inherited standards, such a study is of value. The waves of opinion which are popularly called "fads and frills" can be minimized by a study of past experience with similar schemes. As an instrument for broadening the interests and sympathies of teachers, often far more restricted than those of the children whom they teach, this study is of great value because of the broad conception and wide social relation of education which it gives. When the Herbartian conception of education as the development of many-sided interests upon the part of the pupil is considered, the importance of the same development for the teacher is evident. The greatest professional significance is that the contributions of historical study clarify standard and ideals. Where, as in teaching, no definite purpose, adequate or satisfactory, can be gained either from a knowledge of the subject matter imparted or from the mind of the

child taught, some formulation of ultimate standards is essential. The study of the relation of school work to social needs and various historical stages contributes much to this end. On the technical side, much is to be said for the training in the use of the comparative or historical method as well as for the experimental through psychology or the logical through philosophy. On the cultural side much could be argued for the value of a subject which represents society's conscious attempt to perpetuate its achievements of the past and to realize its aspirations of the future. It is needless to add that these values are not to be found if the subject is to be conceived as a study of schoolroom devices or the pedagogical ideas of a few leading teachers or philosophers. It is only reached when treated, as by Plato and Aristotle, as an essential part of the study of society represented in its highest conscious effort, — the culmination of the social process.

**Historical Development of the Subject** — The study of the history of educational thought and practice did not receive serious attention until the end of the eighteenth century, when it was stimulated by two movements. The first of these was the general interest in the past and a desire to estimate human progress by comparison with the past. Secondly, an impetus was given to a study of antiquity by the revolutionary and rationalistic movements of the age which refused to recognize the influence of the past. Hence the desire by the opponents of these movements to trace the evolution of human progress and establish some standards and norms to counteract what were regarded as revolutionary proposals.

Probably the earliest history of education as such was the *Traité des Choix et de la Méthode des Études* (1675) by Claude Fleury, who was associated with Bossuet as instructor to the royal children. This work was translated into English in 1695 by S. Keble. As Fleury states in the opening sentences of his work that "to understand well the Order of our publick Studies, it seems to me Advisable to go to the Fountain-head; that so we may see whence every part is deriv'd down to us; how the whole body of these Studies has been form'd in the Succession of many Ages." The first part, about fifty pages, is devoted to a history of studies down to the "Restoration of Humanity." The chief interest in this part is perhaps a recognition of the influence of Arabian and Hebrew thought on the Middle Ages. Otherwise the work, as might be expected, is somewhat sketchy. The second part is devoted to a theory of the curriculum. In the century following there appeared many histories of individual schools, but no connected history of education. Among these may be mentioned: Ludovicus, G., *Historia Rectorum Gymnasiorum, Scholarumque celebriorum* (Leipzig, 1908-1911); Biedermann, *Acta Scholastica, Altes und Neues von Schulsachen* (Halle, 1752-

1755); Burckhardt, *De varis Germanæ Scholarum a Caroli M tempore usque ad Sæc. XVI Mutationibus* (1715); Schottgen, *De Statu Scholarum ante Reformationem* (1717); Ulrich, *Pragmatische Geschichte der vornehmsten Katholischen und protestantischen Gymnasien und Schulen im Deutschland* (1780). The author of the last work hopes by a complete account of the qualities and defects of certain schools to lead to improvement and greater perfection of teaching method and discipline in the schools of his day. The work gives an account, valuable because contemporary, of Basedow's theory of the Philanthropinum (f. 1774), a history of the Fürstenschulen of Saxony, and of schools in Austria and Bavaria. It is interesting to note, as bearing out the introductory statement, that the work which has usually been regarded as the first history of education, C. A. Mangersdorf's *Versuch einer Darstellung dessen was seit Jahrtausenden im Betreff des Erziehungswesens gesagt und gethan worden ist* (Leipzig, 1779), was prompted by opposition to the educational thought represented by Basedow. "If one desires," he writes, "to form a correct judgment on new proposals for improving education, one must not only know what has been done in various directions, but also what has been said." This work was followed by the *Geschichte des Schul- und Erziehungs-Wesens in Deutschland von der Einführung des Christenthums bis auf die neuesten Zeiten*, by Fr. E. Ruhkopf (Bremen, 1794). This is an attempt to record the most important steps in the origin and progress of German education. The work is based on source material, and is valuable, bibliographically, for the references to earlier books on education, which, however, contained nothing but biographies, lists of births and deaths, or collections of writings. The author refers to a plan for a History of Education published by Schoppelein in *Magazin für Schulen* about 1770, which was never carried out. He takes a broad view of education, and recognizes the intimate connection of education with the church, politics, and literature, and claims his book to be the first attempt in a new field. A significant step in advance was made by Fr. H. Christian Schwarz, who in 1802 had published *Erziehungslehre*, to which he added in 1813 *Geschichte der Erziehung in ihrem Zusammenhang unter den Völkern von alten Zeiten her bis aufs neueste*. A new edition in 1829 was preceded by the history, since a true conception of present problems is impossible without a knowledge of what has already been done. He is opposed both to the view which looks upon the past as perfect because it is past, and to the view "which holds that truth has never yet been discovered and that every moment brings something better than before." History of education is a branch of the history of civilization, and while giving an account of the past, affords insight into the present. The work is comprehensive, and deals with the educational

history of most of the nations of antiquity up to the philanthropinistic movements and the new education. The importance of the history of education was also recognized by A. H. Niemeyer, who added a historical section (*Überblick der allgemeinen Geschichte der Erziehung und des Unterrichts nebst einer specielleren pädagogischen Charakteristik des achtzehnten Jahrhunderts bis auf die neuesten Zeiten*) to the later editions of his *Grundsätze der Erziehung und des Unterrichts* (1796). Here the history of education is given in outline up to the eighteenth century, which receives more detailed treatment. A separate work, *Originalstellen griechischer und römischer Klassiker über die Theorie der Erziehung und des Unterrichts* (1813) serves to supplement the earlier summary. While the author recognizes the breadth of the subject as an account of the theory of education, the leaders, institutions, and writings of the past, his work gives little more than biographical sketches of educational leaders.

The practical purpose of a study of the history of education, emphasized by Schwartz, was recognized in a number of histories written about 1830. Thus A. Kapp, in *Commentatio de historia educationis et per nostram aetatem culla et in posterum colenda* (1834) would include a study of all types of education in addition to the school, for "the correct historical account of a science or art leads to a clear knowledge of the really true standpoint." He himself was the author of *Platons Erziehungslehre* (1833) and of Aristotle's *Erziehungslehre* (1837). So in the forties most books on the theory of education were preceded by some historical account; as examples may be cited Gustav Braun, *Grundzüge der Erziehungslehre* (1849), and Rosenkranz, *Die Pädagogik als System* (1848).

The history of education was not uninfluenced by the Hegelian philosophy of history. Hegel's own *Lectures on the Philosophy of History*, dealing as it does with the development of human Geist or spirit toward self-realization, may to that extent be regarded as a history of education in its broadest sense. Several works accordingly appeared in this field with a preconceived law of progress to serve as a standard of judgment. Fr. Cramer devoted his lifetime to the study of history of education, but never completed the work. He published in 1832 *Geschichte der Erziehung und des Unterrichts im Altertum*, which in 1839 was brought down to the time of Lucian; and in 1843 appeared his *Geschichte der Erziehung und des Unterrichts in den Niederlanden während des Mittelalters*. He regards as the main aim of education not its purely practical aspect, but a knowledge of the educational means of ancient times, what the human efforts were in all fields, and how the divine idea to bring the human race to perfection has developed and revealed itself in human progress. History should trace the influence of divine providence in the direction of human

affairs without any subjective additions. With K. Schmidt, *Geschichte der Pädagogik dargestellt in weltgeschichtlicher Entwicklung und im organischen Zusammenhange mit dem Kulturlieben der Völker* (1860-1862), the idea of the God-man is the central point in world history, progressive evolution is accordingly the embodiment of God in man, and the history of education attempts to accompany the spirit of man through the struggle for freedom. At the same time this work contains a great deal of material and a full bibliography.

The work of Karl von Raumer, *Geschichte der Pädagogik vom Wiederaufblühen klassischer Studien bis auf unsere Zeit* (1847), is important in a historical survey, for this work more than any other has exercised an influence on the histories of education written in English. Von Raumer began his studies with a course of lectures at Halle in 1822, and continued at Erlangen from 1838 to 1842. While he recognizes that a history of education must keep in view the cultural ideal of the time and show how this ideal was worked over into the practical field of education, he devotes the greater part of his work to biographies of educational leaders as the embodiment of the ideals of their day. Nor does he accept the theory that a history should be an objective account of facts, for if the history of education, for example, is to have any value, it must be approached with subjective problems and standards.

More comprehensive than any of the preceding works is the *Geschichte der Erziehung von Anfang an bis auf unsere Zeit* (1884-1902), issued by K. A. Schmid with the collaboration of many scholars, each one a specialist. The work represents the modern conception of history as an account of facts as they really were and in their actual connection. Systems of education remain unintelligible when freed from the general intellectual atmosphere in which they are set. So extensive a work would have been impossible for one man alone, and it is representative of another modern tendency, not to issue general histories but monographs on special topics and publication of source material. Since Schmid most of the general histories of education have merely been textbooks based on previous works, but an exception must be made in favor of Paulsen's *Das deutsche Bildungswesen in seiner geschichtlichen Entwicklung* (Leipzig, 1906), which, in spite of its short compass, gives a good account of German education as part of the development of German culture. It was pointed out earlier how the first histories of education were histories of individual schools. Valuable special studies were A. Heppe's *Geschichte des deutschen Volksschulwesens* (1858); Grasberger, L., *Erziehung und Unterricht im Klassischen Altertum* (1864); Kehr, K., *Geschichte der Methodik des deutschen Volksschulunterrichts* (1877); Paulsen, F., *Geschichte des gelehrten Unterrichts* (1884). Since then the number has increased rapidly, the most scholarly and valu-

able series being the *Monumenta Germaniae Pædagogica* (q.v.), edited by Kehrbach and issued since 1889. Under Kehrbach's influence was organized in 1890 the *Gesellschaft für deutsche Erziehungs- und Schulgeschichte* for systematic research into the local educational history and the collection and publication of records bearing on education in German-speaking countries. School ordinances, textbooks, biographies, diaries, pictures, etc., are investigated. In addition much local research is carried on, as an example of which may be cited H Heyd, *Geschichte der Entwicklung des Volksschulwesens im Grossherzogtum Baden* (1894-1897), done under the auspices of the Elementary Teachers' Association of the duchy. The following series explain their purpose without any further description: Fr Mann, *Bibliothek pädagogischer Klassiker* (1869-1895); G A Lindner, *Pädagogische Klassiker*, Karl Richter, *Pädagogische Bibliothek*, G Frohlich, *Die Klassiker der Pädagogik*, E Friedrich, and H Gehrig, *Die pädagogischen Klassiker*; R Vormbaum, *Evangelische Schulordnungen des 16., 17., und 18. Jahrhunderts*, A Richter, *Neudrucke pädagogischer Schriften*, H Schutze, *Auslese aus den Werken berühmter Lehrer und Pädagogen des Mittelalters*; Aug Israel, *Sammlung seltener gewordener pädagogischer Schriften des 16. und 17. Jahrhunderts*, Kurz, F X, *Bibliothek der Katholischen Pädagogik*, Von Ufer, *Internationale Bibliothek für Pädagogik und den Hilfswissenschaften*, *Sammlung der bedeutendsten pädagogischen Schriften*. For the history of the universities excellent material can be found in the work of W Erman and E Horn; *Bibliographie der deutschen Universitäten* (Leipzig, 1904), a comprehensive list of works dealing with universities up to 1899. To this may be added the monograph series edited by Th Kappestein, *Die deutschen Hochschulen* (Berlin, 1907-).

**English** — Histories of education in English have in the main followed the work of Von Raumer as a model. Few of them have even attempted to trace the development of education in its broadest aspect as a branch of the history of civilization, and the majority have been content to give accounts of the educational leaders and their theories. Probably the earliest systematic survey in English was given in a small volume issued in *Harper's Family Library* in 1842. The author, H I Smith, Professor of German Language and Literature in the Theological Seminary at Gettysburg, Pa., was evidently familiar with the earlier German works. The volume gives a very creditable survey of educational development, and is superior to many published much later. Barnard, while in general covering the whole of the history of education in different issues of the *American Journal of Education*, either based his contribution on German sources or translated parts of Von Raumer. *German Teachers and Educators* (1878) is an expansion of the

*German Educational Reformers*, collected from the *American Journal* and published separately in 1863, being thus probably the first history of education in English. This had been preceded in 1859 by the translation of Vol IV of Von Raumer, *German Universities*. A similar collection on English education from the *American Journal* was made in 1876, when two volumes, *English Pedagogy*, *The School and the Teachers in English Literature*, were published. This work is of great value for the collection of source material and the light thrown on English education by the quotations of writers who were not professional educators, and has hardly been surpassed up to the present.

Another work which has had and still has a great vogue is R H Quick's *Educational Reformers* (1868), also based largely on Von Raumer; this was expanded in 1890. Here, too, the treatment is confined almost entirely to education of the schoolroom. The aim which Quick had in mind was to acquaint practical men in education with "what has already been said and done by the leading men engaged in it, both past and present" (1868), in a later edition (1890) the aim is stated to be "to select a few people especially worth knowing about and to tell concerning them in some detail just that which seemed to me specially worth knowing." As professor of education in the College of Preceptors, Joseph Payne (q.v.) delivered the first course of lectures on the history of education in English, which aimed at nothing more than a treatment of the art of education at different periods. In general the emphasis which was prominent with the German historians is also found here, to understand the history of the subject as an aid to the solution of modern problems. Few have recognized the comprehensiveness of the educational influences, or, if they have, as Seeley did who saw that the "details . . . embrace a study of the history and environment, of the internal, social, and religious conditions of the people," they have failed to carry them out. The following works which appeared before 1900 may be mentioned. Browning, O, *Educational Theories* (Cambridge, 1881), Painter, F V N, *A History of Education* (New York, 1886), Williams, S G, *The History of Modern Education* (Syracuse, 1892); Munroe, J P, *The Educational Ideal* (Boston, 1895), Seeley, J., *History of Education* (New York, 1899). The appearance of Thomas Davidson's *A History of Education* in 1900 marks an epoch in the conception of educational history in English. This is the first work which is not mainly biographical, and is an attempt to trace educational development as a phase in human evolution. But while trying to avoid the narrowness of earlier histories, Davidson's book errs somewhat in exaggerating the other side without giving a clear definition of education. An attempt to strike the mean by making "evident the relation between educational development and other aspects of the

history of civilization and to deal with educational tendencies rather than with men," is made in Monroe's *Textbook in the History of Education* (1906). While not neglecting the practical aim, to show connection between theory and school practice, and the influence of the past on the present, the work has the advantage of constant reference to source material.

Very little of the nature of the German monographs has been done in English, nor is the interest in the history of education so strong either in England or America as in Germany. A valuable contribution on Education in Early England was made as early as 1867 by F. J. Furnivall in the introduction to the *Babees Book*, but with the exception of Leach's *English Schools before the Reformation* (1896), *Educational Charters* (1911), and his contributions to the Victoria County Histories of England, de Montmorency's *State Intervention in England*, and Watson's *English Grammar Schools to 1660 and Beginnings of the Teaching of Modern Subjects in England*, little has been done toward a comprehensive history of English education, the series of monographs on the colleges of Oxford and Cambridge, and several on the large Public Schools may here be mentioned. In America the field is only just beginning to be studied.

**France** — The history of education is hardly taught in France, and only figures in the curriculum of normal schools. A ministerial decree of Aug. 3, 1881, introduced this subject into the course for the third year in the following terms: "History of Pedagogy, the chief educators and their theories, Analysis of the most important works."

In the universities there are no special chairs in the history or science of education except where occasionally the professors of philosophy or the instructors, few and far between, who fill a chair in the science of education, devote their courses to the history of a period in education or to some educational topic. It was in this way that the present writer as professor of philosophy in the faculty of letters of the University of Toulouse, took education as the topic of his lectures, which resulted in the two volumes on the *History of Educational Theories in France*.

In the secondary schools, *lycées* and *collèges*, no attention is paid to the history of education, but the candidates for the various *agrégations* (*q v*) must study at least some sections. The decree of July 26, 1900, which regulates the requirements in the practice of education which candidates must attain to be permitted to present themselves for the competitive examination distinguishes between the practical apprenticeship as assistants in a number of classes in the *lycées* and preparation in theory by attendance at twenty conferences dealing with secondary education in general, its history and organization in France and abroad.

Thus the history of education is not a regular subject of instruction in France. For a long time those who were inclined to study it had only the German authorities at their disposal. Thus Fritz, in giving a survey of the works on history of education (in *Esquisse d'un Système complet d'Instruction et d'Éducation et de leur Histoire*, Vol. III, ch. I (Strassburg, 1843), refers in the main to German works and only mentions one in French (Guizot, *Essai sur l'Histoire et sur l'État actuel de l'Instruction publique en France*, Paris, 1816). A year after Fritz's work there appeared *Histoire critique et législative de l'Instruction publique et de la Liberté de l'Enseignement en France* by H. de Riancey (Paris, 1844), which aimed with the help of a survey of educational history to establish some standards for further reform. But the contributions to the subject in France were very small until the eighties, since when a large number of works, the majority dealing rather with French history, and particularly the period during or subsequent to the Revolution. The standard work until this period was that of Jules Paroz, *Histoire universelle de la Pédagogie* (Paris, 1867).

The time has gone by when the efforts of the Revolution in educational matters can be ignored, or when a French university scholar, like Théry, in his *Histoire de l'Éducation en France*, can open the chapter on the Revolution with these contemptuous words, *On n'étudie pas le vide, on n'analyse pas le néant*. It is precisely this period in our history, which with the Report of Talleyrand to the Constitutional Dynasty, of Condorcet to the Legislative Assembly, of the plans of Mirabeau, Lakanal, Daunou, has been one of the most productive, preparing the ideas which have been assured their accomplishment in the Third Republic. Collections of important documents have been published which enable scholars to investigate the educational part, of these the most notable is the work of Gréard (*q v*), *La Législation et l'Instruction primaire depuis 1789 jusqu'à nos Temps*, including laws, decrees, and ordinances preceded by an introduction. Gréard was one of these who contributed greatly to spreading a taste for the history of education in France, especially by his excellent studies of the most celebrated educators, Mme de Maintenon and Mme de Rémusat, and by his introduction to Fénelon's *Éducation des Filles*. Mention must also be made of M. F. Buisson, the second edition of whose *Dictionnaire de Pédagogie* has just appeared, giving a careful treatment of the history of education and articles on the most important educators. The author's own *Histoire de la Pédagogie* has been translated into English by W. H. Payne, as well as a few volumes of his series *Grands Educateurs* (*Pioneers of Education*, London, 1908).

**HITCHCOCK, EDWARD** (1793-1864) — College president and scientist, was born at Deerfield, Mass., on May 24, 1793. He received his education in private schools and at Yale College. He was principal of the Deerfield Academy (1815-1818), professor of chemistry and natural history in Amherst College (1825-1844), and president of Amherst College (1844-1854). He served as state geologist of Massachusetts, and was one of the founders of Mount Holyoke College (*qv*). His writings include *Life and Labors of Mary Lyon* (1852), *Reminiscences of Amherst College* (1863), and several works on geology and botany.

**HOAR, LEONARD** (1630-1675) — Third president of Harvard College, and a prominent clergyman and physician, was graduated at Harvard in 1650, and subsequently took a degree in medicine at the University of Cambridge, England. He succeeded Chauncy as president of Harvard in 1672. "As a scholar and a Christian he was very respectable, but being deficient in the spirit of government, and falling under the displeasure of a few men of influence in the neighborhood, the students were thus encouraged to array themselves against him, and his situation was rendered so unpleasant that he was under the necessity of resigning his office March 15, 1675." He advocated technical and industrial education as a part of the college course.

**HOBART COLLEGE, GENEVA, N.Y.** — The successor of Geneva Academy. In 1860 the present title was adopted. Though largely aided by Protestant Episcopal Societies and individuals, the college is nonsectarian in ad-

ministration. Hobart College is among the institutions originally accepted by the Carnegie Foundation for the Advancement of Teaching (*qv*). The institution confers the usual bachelor's degrees in arts, philosophy, and science, and the degree of A. M. for one year's graduate study in residence. Admission is by examination or certificate from an approved four-year high school. In September, 1908, the trustees of Hobart College opened William Smith College for the separate instruction of women, founded through the gift by William Smith, Esq., of Geneva, of \$475,000. The work of the two colleges is conducted independently by a common faculty upon whose recommendation the corporation of Hobart College grants to the students of both institutions the same degrees. There was in 1910-1911 an enrollment of ninety men and thirty-eight women, with a faculty of twenty-three members.

C. G.

**HOBART, JOHN HENRY** (1775-1830) — Founder of Hobart College (*qv*), was educated at the University of Pennsylvania and Princeton University. His life was devoted to the ministry and episcopacy of the Protestant Episcopal Church. In 1821 he established an academy and divinity school at Auburn, N. Y., which four years later became Hobart College. He was the author of several works on religion and religious education.

**HOBBS, THOMAS** (1588-1679) — Son of an illiterate clergyman of the English church. He was brought up by an uncle, a glovemaker in Malmesbury. Hobbes' education began at four years at a school in Westport, where he mastered Latin and Greek at an early age and was able to translate the *Medea* of Euripides into Latin iambic verse before he was fourteen. Entering Magdalen Hall, Oxford, at fifteen, he received his bachelor's degree in 1608. He seems to have had little sympathy with the pronounced Calvinism which prevailed in Oxford under Dr. Wilkinson, and was left very much to his own devices in his university course. Later he became tutor to the son of the Duke of Devonshire and throughout his life retained his connection with the family, with the exception of two breaks. During the Protectorate he was appointed tutor of the Prince of Wales, then in exile in Paris, where Hobbes became a member of the learned coterie which gathered about the genial Père Mersenne. He also traveled much in Europe and acquired considerable acquaintance with the mathematical and physical sciences and philosophy of the continent. His devotion to the cause of the English monarchy and nobility, however, rendered him unpopular among the leaders of the Puritan uprising, and gave a decidedly political

cast to all his more important speculations, thus illustrating a characteristic tendency of English philosophy. For if Hobbes be "the father of English psychology," he also led the way in teaching that intellectual activity should, in aim and application, be practical.

Not long before the opening of the Long Parliament (1640) he wrote his works entitled *On Human Nature* and *De Corpore Politico*. At Paris he wrote others, including his masterpiece, *Leviathan* (1651), which is a treatise on social polity. It was, therefore, not until his fiftieth year that the germ of his system began to fructify, in which the following points are to be noted. (1) Hobbes sought a philosophical foundation for his doctrine in the idea of motion. With this as a starting point he believed that the whole body of knowledge could be disposed of in three sections under the headings of Body, Man, and Society. (2) Accordingly, in the work *De Corpore*, the idea of body is examined. Here he anticipated Leibnitz by attributing an atomic structure, endowed with potentialities of feeling, to matter. He explained natural or physical phenomena in terms of the universal laws of motion, as motion had been mechanically explained by Galileo and others. (3) In *De Homine* he sought to deduce all subjective experience from sense, as sense is physically determined by the body and its motions. All knowledge, therefore, grows out of sensations. After sensation there remains behind the memory of it, which may reappear in consciousness, and, aided by signs (words, general notions, definitions, and mathematical formulæ), be communicated to others. All thought is merely the addition and subtraction of sense perceptions. (4) In *De Cive* he attempted to bring both society and man within the same principles of scientific explanation as he found applicable to nature, being the first Englishman to make such an attempt. This part of his doctrine starts with the idea that all human beings are at war with each other. But this state of things is so unsatisfactory that there is all the more need of an absolute ruler, king or assembly, whose authority shall be law and to which all are compelled to render unconditional obedience by formal contract. Right and wrong are thus merely the conduct which the State sanctions or punishes. Even religion is a State-regulated convention, from which there is no appeal.

The great work of Hobbes, *Leviathan*, is an elaboration, in a more popular form, of his theory of the commonwealth, and it is in this work that he touches on the question of education. For in it he attacked violently the universities and their systems, maintaining (1) that by their allegiance to the Puritan cause they were subverting public order; and (2) by their adherence to the old learning they were working social mischief. A bitter controversy was aroused by these charges, which Dr. Wallis, of Oxford, succeeded in meeting. As a reply

to Wallis he published his *Six Lessons to the Professors of Mathematics* (1656), in which he explains his anti-Euclidean view of geometry. This he followed by other smaller works on the same subject, written in a controversial style, which, however, did not add greatly to his reputation as a philosopher.

Hobbes was a man of immense energy, untiring activity, and regularity of life. Some idea of the range of his interests can be gathered from the fact that he translated Thucydides and at eighty-five turned four books of the *Odyssey* into English rhymes, adding later the *Iliad*, to which he prefixed an essay on the nature of heroic poems.

**HOCKEY, FIELD.** — This is one of the few team games played by men and women. Although its origin goes back to the fourteenth century in France, hockey was developed in England, the home of nearly all modern athletic games. It is the favorite winter sport among English women and is gaining in popularity among men. The game was introduced to girls in American schools and colleges in the autumn of 1901. It was received with so much interest and enthusiasm that it soon won a permanent place in the athletics of schools and colleges for women. Field hockey is a splendid, healthful game; its effect upon the players is to develop vigor, endurance, and mental alertness. It offers to girls essentially the same advantages that boys derive from football, lacrosse, and ice hockey.

The game is played by two teams of eleven players — five forwards, three half backs, two full backs, and a goal keeper. The outfit con-

sists of a hardwood stick which has a blade about a foot long, bent at an angle of forty-five degrees from the handle, which is about two feet long. The ball used is a cricket ball or a solid rubber ball painted white. The game is played on a smooth field a hundred yards in length by not less than fifty yards nor more than sixty yards in breadth. This space must be marked out with whitewash lines and with a flag at each corner. The longer lines are called the "side lines" and the shorter ones the "goal lines." Transverse lines are marked in the centre and midway between the center and the goal lines. Five yards inside each side line is marked a dotted line, parallel with the side line, this is called the "five-yard line." In the middle of each goal line, and four yards apart, are placed the goal posts. These are uprights seven feet high with a cross bar on top and a net forming a pocket behind the posts and crossbar. In the front of each goal line and fifteen yards from it is drawn a line four yards long, parallel to the goal line. The ends of this line are carried round in a curve, forming a quarter circle, until they reach the goal line at a point fifteen yards from the center of the goal. This half circle is called the "striking-circle."

**HOCKEY, ICE.**—A strenuous and fascinating game developed in Canada during the last quarter of the nineteenth century. The English game of field hockey and the old game of "Shinty" or "Shinny" contributed the essential principles of the modern game of Ice Hockey. In the United States this game is played by boys and young men in schools and colleges where the climate permits of ice skating during the winter months. It is played on a rink about 80 by 180, or 100 by 200 feet surrounded by a wooden wall about two feet high. At each end is a goal made of two posts four feet high and six feet apart. The game is played by teams of seven players—four forwards, one on each wing and two in the center, a cover-point, a point, and a goal keeper. The players use high, long, and strong skates, and a bent stick made of ash or hickory. The stick has a blade about a foot long and three quarters of an inch thick, bent at an angle of forty-five degrees from the handle, which is three and a half feet long. The game is to push and drive a puck into the goal. The puck is circular, one inch thick, three inches in diameter, and made of vulcanized rubber.

The rules of the game resemble those of American football; the player must be "on side," and the puck must not be passed forward to another player. As played in the United States and Canada, it is a rough and strenuous game. A good hockey player must

be a fine skater, and possess strength, agility, pluck, good judgment, and endurance. Hockey is a splendid game to develop physical vigor and manly qualities when properly played, but like basketball, and football it degenerates into a rough and sometimes brutal game when not properly supervised. Students should not be permitted to engage in this sport unless they have been examined by a competent physician, and declared free from disease or organic weakness.

There is a real need for such games as ice hockey, football, and basket ball for the best physical and moral development of healthy boys and young men, but these games require most careful supervision by educational authorities to insure beneficial rather than harmful results.

**HOGG, QUINTIN** (1845–1903) — English social reformer and founder of the Regent Street Polytechnic, was born in London, February 14, 1845, the fourteenth child of Sir James Weir Hogg, Baronet and Privy Councillor. Quintin Hogg was educated at Mr. Lee's preparatory school at Brighton and at Eton (1858–1863), where he showed intellectual promise, was very popular with the boys on account of his athletic distinction and public spirit, and founded in Joynes' boarding house a Sunday Bible Class and prayer meeting which went by the name of the "Synagogue." England was moved at the time by a strong religious revival, and Hogg, most manly of boys, had an unique influence upon the life of his contemporaries at Eton. In 1863 he went into a tea merchant's business in Mincing Lane, in the city of London, and was touched with sympathy for the wastrel boys whom he saw in the streets. Impressed by some experiences with these, he devoted himself zealously to obtaining first-hand acquaintance with their class, and, disguised as a shoeblack, he spent nights with poor boys, frequently sleeping in the open or under arches. The beginning of the Polytechnic may be traced to his efforts to teach reading, with the Bible as a textbook, to two crossing sweepers.

With his friend Arthur (afterwards Lord) Kinnaid, he hired a room in Of Alley (now York Place, Charing Cross) and started a ragged school (*q.v.*). He and his friend held prayer meetings for the Covent Garden porters and classes for the flower girls at Charing Cross. All this time Quintin Hogg was mastering the details of his own business and taking a leading part in the athletic life of Eton and of Lon-

don. In 1868 he traveled in the West Indies and the United States and formed a strong admiration for the Americans. In 1871 he married the daughter of William Graham, a famous collector of pictures. For nearly thirty-two years Hogg and his wife devoted their leisure and a great part of their fortune to work among young people in London. Their experience in the United States and Canada made them strong advocates of supervised, selected child emigration. In America Hogg met D. L. Moody, whose subsequent work in England he did much to forward. The Ragged School, which had been moved first to Castle Street, W. and then to Long Acre, became the center of a widely extending philanthropic work. Mr. Robert Mitchell acting as secretary from 1872 onwards. Trade classes were organized with the aid of grants from the Science and Art Department, and the combination of educational with religious work was the distinctive feature of Hogg's policy. In 1881 he purchased the buildings of the Polytechnic, an institution famous in its time but then in decrepitude, which had combined instruction and amusement for the young. This was the first of the London Polytechnics (*q.v.*), which are institutions under public management for the provision of instruction, recreation, and social intercourse for young men and women of the wage earning and lower middle class. Hogg lived in Cavendish Square, in a house which adjoined the Polytechnic at the back. In order to make use of the rooms which lay empty in the daytime, a day school was established at the Polytechnic in 1886. The large annual deficit on the working of the Polytechnic was met from Quintin Hogg's private purse.

Hogg's life was given to the fusion of the two ideals of Christian service and educational organization. When his work came to maturity, the Elementary Education Act, 1870, had already provided a stronger, though still imperfect substructure for technical instruction. The religious revival had moved some of the rich to a new sense of public duty. Collectivist thought had diffused an ideal of social unity in civic enterprise. The timeliness of Hogg's work lay in the convergence of these different currents of thought and opportunity.

But educational work on a scale so large as Hogg's could not permanently depend upon private liberality. Its very importance not less than its financial needs necessitated public endowment and representative control. In 1878 a Royal Commission was appointed to inquire into the condition of the parochial charities of the city of London, many of which, though wealthy, had become obsolete in application. In 1883 the City of London Parochial Charities Act was passed and directed the Charity Commissioners to frame new schemes for the application of city charities in such a way as to promote the welfare of the poor of the metropolis by education, free libraries, open

spaces, and otherwise. The work of the Polytechnic attracted the attention of the commissioners, and large subsidies were promised from the city parochial funds, including a capital grant of over £11,000 to the Regent Street Polytechnic and a yearly endowment of £3,500, on condition that supplementary resources were obtained from the public. Quintin Hogg now for the first time appealed for subscriptions. The fact was disclosed that his personal expenditure upon the Polytechnic alone had amounted to £100,000. Public opinion was heartily responsive and in the course of a few years ten new Polytechnic institutes, with four branches, were established in London in imitation of the work which Hogg had set going in Regent Street.

Hogg, still immersed in the work of the Polytechnic, died suddenly on January 16, 1903. At the "Poly," as the Polytechnic is known to its members, the memory of "Q. H." will always remain in affectionate remembrance. Hogg's work was one of the causes which, at a critical time, prevented a breach between religious activities and educational developments in England. It now needs to be supplemented (1) by the systematic organization of continuation classes for adolescents, and (2) by an enlargement of the resources of the University of London and its more scientific adjustment to the educational needs of the metropolis.

#### HOLBROOK, ALFRED (1816–1909) —

Normal school principal, son of Josiah Holbrook (*q.v.*), was educated in the public schools of Massachusetts and at Groton Academy. He was for several years principal of the Western Reserve Teachers' Seminary, and in 1855 he founded the Southwestern Normal School at Lebanon, Ohio, which ultimately assumed the name of National Normal University. He was president of this institution for fifty years. He wrote *Methods of Teaching, School Management*, and an English grammar.

W. S. M.

#### HOLBROOK, JOSIAH (1788–1854). —

Founder of the Lyceum movement (*q.v.*) in the United States and organizer of one of the earliest industrial schools, was educated in the district schools at Derby, Conn., and graduated at Yale College in 1810. He organized an industrial school at Derby in 1819, after the pattern of Fellenberg's institution at Hofwyl; and in 1824 he established an Agricultural Seminary at Derby, in which, besides the customary secondary school studies, surveying

## HOLIDAYS

and practical agriculture were taught (See AGRICULTURAL EDUCATION.) His most important service to education, however, was the development of the lyceum movement which resulted in the organization of lecture courses, the establishment of libraries, and the equipment of schools with scientific appliances in hundreds of towns in the country. (See AMERICAN LYCEUM ASSOCIATION.) In 1826 he opened an educational exchange in Boston for the manufacture and sale of school apparatus. In 1830 he began the publication of a series of *Scientific Tracts* for the use of teachers and advanced students. In the next year he was active in the organization of the American School Society (qv). In 1832 he founded *The Family Lyceum*, a weekly paper for the diffusion of useful knowledge. He lectured widely before lyceum associations on scientific subjects, and was a frequent lecturer at teachers' institutes conducted by Horace Mann in Massachusetts and Henry Barnard in Connecticut. He was also active in the American Institute of Instruction (qv) and the various educational associations in New England, New York, and Pennsylvania.

**HOLIDAYS, SCHOOL** — In the United States the public schools in cities usually begin in September and continue until May or June. The common term in the North Atlantic and North Central groups of states is from 180 to 200 days in the cities, 140 to 160 days in the village or town, and 100 to 140 days in the rural schools. The shorter the term, the longer the summer vacation. Nearly all town schools begin by October, the term being shortened at the end. During the regular school year certain holidays are commonly granted, the most common and universal of which are every Saturday and Sunday in full, Thanksgiving Day, on the last Thursday in November, and commonly the Friday following it; from ten days to two weeks covering Christmas and New Year's, and from one or two days to a week at, or near, Easter. Other general holidays frequently observed as school holidays are election day, coming early in November in alternate years; Washington's birthday on February 22; and Memorial Day on May 30. Admission Day is observed as a holiday in some states; Columbus Day (October 14) is being declared a school holiday in many states; and Lincoln's birthday (February 12) is also frequently observed in the Northern and Western states in whole or in part as a holiday.

On the continent of Europe Saturday is seldom a whole holiday. In Germany schools are commonly in session six mornings a week,

## HOLLAND

with from two to four afternoons in addition. Wednesday and Saturday afternoons are commonly half holidays. About ten weeks of vacation are allowed each year in German schools, in addition to certain church festivals. In Prussia and most of the northern states two weeks are given at Easter; about one week at Whitsuntide, four weeks in the summer, mostly in July, two weeks at Michaelmas; and two weeks at Christmas. Bavaria, where the summers are warmer, has no vacation at Whitsuntide and only one week at Christmas, but about eight weeks in summer. The church festivals of Epiphany, Candlemas, Annunciation, Corpus Christi, *Peter-Paulstag*, All Saints, and Conception of the Virgin are observed in Catholic countries, the *Reformationsfest* in German Protestant schools, and the birthdays of the reigning sovereigns commonly in all monarchical countries. Not to be omitted are the holidays given when the thermometer registers twenty-five degrees Celsius at ten o'clock A. M. (*Hitzefreiheit*), at the discretion of the school principal or the local school inspector (*Ortschulinspektor*). In France the week-holiday is on Thursday, Saturday being a full school day. The summer vacation is of about two months' duration, with short vacations at New Year's and Easter, and on certain religious and national holidays.

In England the common practice in elementary schools is to give about two months of vacation throughout the year, usually divided as follows: three to four weeks in summer, two weeks at Christmas, one week at Easter, and one week at Whitsuntide. Special holidays are unusual, although a movement is on foot to introduce the general observance of Empire Day in schools. In the secondary schools twelve to fifteen weeks in each year are given up to vacations, of which six or seven weeks are taken in summer, three or four weeks at Christmas, one to three weeks at Easter, and in some cases, especially in the North, one to two weeks at Whitsuntide. In addition most schools recognize a mid-term holiday of one or two days, and one or two half holidays in each week or a whole holiday on Saturdays. Special holidays are observed on Founder's Days in the older schools, and occasional half or whole holidays are given to celebrate any distinctions won by a school either in scholarship, athletics, or the more solid distinctions of later life.

**HOLLAND.** — See NETHERLANDS, EDUCATION IN THE.

**HOLLAND, PHILEMON** (1552-1637). — An English schoolmaster and translator, who practiced medicine for some time before he

became usher in Coventry Free School in 1608, and then headmaster (1627-1628). He played an important part in the civil life of Coventry, and was given the freedom of the city in 1612. The "translator Generall in his Age" (as Fuller calls him) was familiar with Latin, Greek, Italian, and French, and had a good command of the euphuistic style in English which was then popular. His translations were somewhat free, since he worked on the theory that "each nation hath severall manners, yea, and terms appropriate by themselves." He translated so many books, according to Fuller, "as will make a country gentleman a competent library for historians." These translations included Livy (1600), dedicated to Queen Elizabeth, Pliny's *Natural History* (1601); Plutarch's *Morals* (1603); dedicated to James I, Suetonius' *Twelve Caesars* (1606); Camden's *Britannia* (1610); and Xenophon's *Cyropædia* (1632).

**HOLMES, GEORGE FREDERICK** (1820-1897) — College president and textbook author, was educated at Durham University, England, and came to America in 1838. He taught in secondary schools in Virginia and Georgia, was professor in Richmond College (1845-1848), first president of the University of Mississippi (1848-1849), professor in William and Mary College (1849-1857) and the University of Virginia (1857-1897). He was author of an extended series of textbooks widely used in the South, and of several historical works. W S M.

**HOLMGREN TEST** — A method of testing the ability to discriminate between colors. A large number of differently colored worsted skeins, thoroughly intermixed, is shown the subject to be investigated. The experimenter selects one of these, and, giving it to the subject without naming its color, asks him to pick out from the others, one by one, all worsteds of similar coloring. The normal subject does this rapidly and without error. The subject with defective color vision will, however, if the color given him to match falls within his defect, show such hesitancy in selecting and such uncertainty in his matches that the experimenter may, on this account alone, well be suspicious. But in addition to the uncertainty, he will make positively wrong choices. There are two main tests, — the green test and the red test. For the first a bright, low-saturated green, neither yellowish nor bluish, is given as the test color. The red-green color-blind person will then chiefly choose, as similar colors, the grays, the browns, and the slightly reddish, yellowish, and bluish hues. For the red test an unsaturated

red is chosen as the test color. The errors will include worsteds tinged with violet, and greenish and brownish hues. Sometimes one of these tests will suffice, sometimes both are needed. In one or the other, however, both types of the red-green color-blind will with fair certainty betray themselves, as well as those commonly termed "color-weak." The yellow-blue color-blind will choose a bluish red as similar to a yellowish red or a bluish green as similar to a yellow-green. It has been found, however, that many of the "color-weak," and even of the color-blind, may, especially with practice, successfully pass the Holmgren test, in cases of doubt, therefore, one of the more exact tests should be given. See EYE, NAGEL'S TEST

**HOLT, JOHN** — The writer of a very early Latin grammar, the *Lac Puerorum, or Mylke for Children*. Holt was master of the school attached to Magdalen College, Oxford, a school renowned for its teachers of grammar, including such men as Anwykyl, Stanbridge, Robertson, and Cooper. Dr J H Lupton (*Life of Colet*, p 24) thinks that the earliest undated edition of Holt's book was published between 1486 and 1496. The earliest dated edition appears to be 1497, thirty years before Colet's *Aditio* (1527), which was the basis of Lily's *Grammar*. The simplicity of Holt's grammar is remarkable, being written in the easiest English, clearly with a view to helping children. The earliest printed Latin grammars were in English, the use of Latin in the textbooks was established by Lily and the later grammarians and was a constant cause of disagreement amongst English teachers. Holt begins with the names of parts of speech, and proceeds to the declension of the article. With the aid of woodcuts representing a hand or similar device, he illustrates the different cases or declensions by labeling different parts with the appropriate names. In a businesslike, sensible and concise way Holt goes through the whole of the accidence. Thus in dealing with the moods of the verbs, he calls them the showing mood or indicative, the bidding mood or imperative; the willing mood or optative, leaving the infinitive undescribed. Then he proceeds to the simple statement of the concord, the ablative absolute, construction of verbs with diverse cases, and other important constructions, all being arranged so as to give the pupil the most important as well as the shortest teaching. The book ends with epigrammatic verses of Sir Thomas More in praise of Holt's book. F. W.

**HOLY CROSS COLLEGE, NEW ORLEANS, LA** — A school for boys conducted by members of the Congregation of the Holy Cross, established in 1879. Commercial and classical courses are offered.

**HOLY CROSS COLLEGE, WORCESTER, MASS** — See JESUS, SOCIETY OF, EDUCATIONAL WORK OF.

**HOLYBAND or HOLLIBAND, CLAUDE** (pseudonym of Claude de Samliens or A Sancto Vinculo) -- French Huguenot refugee in England, came to England in the second half of the sixteenth century, at any rate by 1566, and remained there till 1597. He played an important part in the development of French studies in England. In 1566 Holyband published his *French Littleton*. This was intended to appeal specially to lawyers and students of the Inns of Court, and was published by Holyband's Huguenot compatriot, Vautrollier. In 1573 an edition of Holyband's *French School-master* was published (the first edition, of which no copy is known, is said to have been issued in 1565). This contains dialogues on such subjects as Getting up in the morning, Two neighbours meeting, Welcoming any one to a house, To ask the way, To ask for a lodging, To go to bed, To buy and sell. Then follow, Proverbs, Creed, Ten Commandments, Graces, etc. In 1580 Holyband wrote his *Treatise for declining of (French) Verbes* and his *de Pronunciatione Linguae gallicae* (in Latin) in the same year. In this year (1580) also, he published *The Treasure of the French Tongue, teaching the waye to maie all sortes of Verbes; enriched so plentifully with Wordes and Phrases*.

In 1593 the *Treasure* was developed into *A Dictionarie, French and English*. This was the most important French dictionary which had appeared, and Miss Lucy E. Farrer has shown that a copy was by 1608 augmented by Randle Cotgrave (*qv*) and in 1610 handed over to Islip the printer, who issued the complete work as Cotgrave's *French-English Dictionary* in 1611. Holyband thus deserves a high place in the history of French studies in England, and is an interesting example of the close connection of the immigration of religious exiles with the teaching of their native language in the country of their adoption, partly of course because schoolmasters often took an important part in the religious controversies of their time in their own country, and when exiled continued their old avocation of teaching for a living.

**HOME AND COLONIAL SCHOOL SOCIETY.** — This society was founded by John Stuckey Reynolds (1791-1874), a retired civil servant, in 1836, though in the course of a few years his original plans were several times modified. (1) The first title, "The Home and Colonial Infant School Society," corresponded with the first purpose, the training of infants' teachers. A widening of the purpose was indicated in 1845, when the words "and juvenile" were added after "infant," but the new title proved too cumbersome for daily use, and it was in 1848 reduced to its final form, "The Home and Colonial School Society." (2) At the outset the students were not required to belong to any particular denomination if they held "the fundamental truths of the Bible" and were "of decided piety," though the committee in their first report seem to regret the preponderance of Dissenters among the students. In 1841 the object of the society was (as it still is) stated to be "the improvement and extension of education on Christian principles, as such principles are set forth and embodied in the articles of the Church of England." In 1846 critics were informed that the committee "some years ago deemed it expedient to provide" separate houses for Church and Dissent, that these houses were "at a moderate distance from each other," and that the students met "only during school hours and for lessons." The critics, however, were not silenced, and in 1848 a rule (now the thirteenth of the society's "Laws") was passed, prescribing that "all individuals appointed to reside" in the college should sign a declaration of conformity with the Church. (3) As Reynolds accepted Wilderspin's theory that an infant school ought to have both a master and a mistress, married couples were specially invited to become students. At first the invitation was readily accepted, but in 1847 the committee reported that the supply had diminished and that "these circumstances" had "necessarily led to the training and employment of females almost exclusively." (If they had waited a year or two, they could have omitted the "almost.") (4) The first home of the society was in Southampton Street, Holborn, London; but after two years the college was removed to Gray's Inn Road, where, with repeated enlargements of its borders, it remained till 1903.

The Rev. Charles Mayo (*q.v.*), one of the earliest English disciples of Pestalozzi, was an original member of the committee, and through his influence the principles of the Swiss reformer were included in the curriculum. He died in 1846, but the good work was continued by his sister, who wrote several textbooks and for many years supervised the professional training. The *Seventy-Fifth Annual Report* of the Society says that "the principles of Pestalozzianism which it strove to inculcate and extend have long since incorporated themselves in some form or other into every department of the training of the young, and are therefore no longer so distinctive as they were, say, fifty years ago."

When in 1846 state grants were offered to Training Colleges, the committee resolved to accept them. As some of the students had, almost from the beginning, been prepared for teaching in nurseries or in private schools, the operations of the society were divided into two departments (still subsisting), a "government department" and a "non-government department." The premises in the Gray's Inn Road, being only adapted houses, could never have reached a high standard of comfort or convenience, and as the standard rose faster than improvements could be made, the Committee determined to migrate to the suburbs. Large and imposing buildings surrounded by fourteen acres of fine grounds were bought at Wood Green, where in 1903 the college entered on a fresh career of usefulness and prosperity.

**HOME GEOGRAPHY.** — See GEOGRAPHY.

**HOME STUDY, HYGIENE OF.** — An important function of school instruction is to develop interests that will determine and guide the pupil's activity outside of the school. For the attainment of this end home study is an important means. While hygienists strongly condemn excessive home work and the evils of worry and anxiety often connected with it, the desirability of a certain amount of home study, especially in the higher grades, is now generally recognized. With home study it is, of course, necessary that the home conditions should be hygienic. The wholesome habits developed in the school should not be broken

by unhygienic work at home. Pupils should sit in correct posture and hold the book at a proper distance from the eyes; they should work for rational periods of time; they should breathe pure air, not overheated or too dry. All the commonplace but important rules of hygiene for intellectual work should be observed.

For many years there has been great conflict of opinion among educators in regard to the kind and amount of home study that is desirable. Recently special investigations have been made by Schmidt and Mayer, which bring out certain factors that are likely to be overlooked. It appears that in our large cities frequently there is really no home, because a whole family may be crowded into one or two basement rooms, an attic, or the like, and suitable conditions for home work are out of the question. Again it is shown that in most subjects children working in a group of other children do more and better work than in the relative isolation of the home. Certain kinds of work, however, seem to be done better in the home when the conditions are hygienic, especially work requiring independent thinking, like composition in the mother tongue, for example. Schmidt's studies show apparently that the ordinary disturbances in the home from the presence of the other members of the family, the noise of domestic work, and the like, do not serve as distracting stimuli for ordinary children. And thus it would appear that for some kinds of work in a moderate amount there are distinct advantages in home study, but that for most of the school work, especially the more mechanical part, the conditions are more favorable in the schoolroom.

The practice of students in regard to home study differs greatly in different countries and in different grades of the school, and individual variations are likely to be very great, some children studying none at all, others perhaps several hours a day. There is grave danger that the best students will overwork. Kemsies, Griesbach, and Roller in Germany and Patzak in Austria found some students in the higher classes of the secondary schools who spent four or five hours daily in home study. The regulations and customs in different countries in this matter also differ greatly. There is probably, however, a consensus of hygienists that home work should be limited and in regard to the points included in the school regulation at the city of Zurich. For the secondary schools it reads as follows: "The home work must be thoroughly prepared for by the instruction. The repeated copying of the same task as a punishment is inappropriate. From the forenoon to the afternoon of the same day no tasks may be given. For Sundays and holidays, as well as the vacations, no more tasks are to be given than from one day to another. Where several teachers give instruction in the same class, there should be an understanding in

regard to the number and extent, and a proper division, of the home tasks " W. H. B.

**HOMER** — The name Homer means to us the *Iliad* and the *Odyssey*, the two Greek epics with which occidental literature begins. It is generally agreed that these earliest poems of Europe are also the greatest. A fact so striking, while it raises questions that cannot be answered, itself goes far to justify the place which Greek has held in occidental education, if literature should have in education any considerable place. These epics are also a poetic picture (not a scientific description) of a historical period, an early stage in the development of European society. In this sense they may be called the beginning of European written history, though they are fiction. Archaeological finds, as idols, utensils, artistic handiwork, lordly dwellings, also throw light on the life of which they are the product, and are a parallel to Homer on this side, at some points perhaps of more scientific value, but for most people these fragments have less interest than the poet's whole.

Such highly wrought compositions, of nearly 15,000 and 12,000 lines respectively, must have had predecessors, though none survive. First, the meter is not that of rude beginnings. The dactylic hexameter is bound by strict laws, yet is flexible and expressive, and is employed with a mastery that speaks of long practice, it was probably formed long before Homer, by the slow welding of two more primitive short verses. The language also is not the unmixed speech of one region and a single period; it is a literary dialect, as truly as the language of Tennyson, combining for artistic use forms and phrases that in living speech had belonged to distant localities and distinct generations and that bear the marks of long poetic tradition. Again, into the tale itself are skillfully woven some elements that are shown to have originated,

and been highly elaborated in verse, in widely separated parts of Hellas. Finally, there are allusions in the poems to earlier heroic lays, tales of famous deeds, and to songs of labor and of festival, and of mourning. Far from being themselves primitive, the two poems are the culmination of a long development, the product of an age of high poetic culture and informed with the distinctive qualities of the greatest Hellenic art, however undeveloped the people may have been in other respects. The date of the poems is unknown, by inference and conjecture it may be placed about 1000 to 800 B C.

The *Iliad* is probably slightly the earlier. The title *Iliad* seems at first inappropriate, only a small part of the war against Ilios, another name for Troy, is included. Yet around the account of the wrath of Achilles and its consequences the poet groups a sufficient account of the origin and of typical incidents of the war to represent well the nature and spirit of the whole. The name is after all not an artistic fault. The subject of the *Odyssey* is the return of Odysseus after the fall of Troy.

The two poems together present a wide range of human life under forms both simple and typical, so elemental that they are in essence true for all ages. And this is done with dignity, with a purity of taste that rarely errs, with a rapid movement that is never hurried, with a charm that holds the reader as it held the ancient listener of every class. In Greek education, from the earliest of which we know anything, the *Iliad* and *Odyssey* were the school-books most widely used. The language was almost as antique by the fifth century B C as that of Chaucer to us, it therefore gave the Greek boy a little of the philological training that comes with the study of a foreign tongue, and was at the same time the basis of all later poetic language, so far as that differed — and it always differs — from daily speech. The substance also of the poems entered into all later Greek literature.

Were these masterpieces the work of one master, Homer, or of two, or of a group or school of popular poets? How did the *Iliad* and *Odyssey* come into being? That is the *Homeric question*. The two poems have about as much likeness and difference as two novels of Scott or of Thackeray have. If one supreme poet of that age is a marvel, still more are two. And yet more marvelous would be a whole school of poets, of more than one generation, all working in the same spirit, all anonymous, who should by any kind of joint activity, contemporaneous or successive, produce two such extraordinary works of genius. Yet it is true that each poem, while essentially a unit, contains incongruities not easy to explain. We must certainly admit later additions and interpolations, of considerable extent in the *Iliad*, less in the *Odyssey*. After more than a century of active investigation and vigorous discussion,

beginning with the *Prolegomena* of Wolf (1795), scholars are tending toward definite acceptance of one poet, wholly unknown except in the poems, with moderate additions and changes by successors and imitators, through whom, mainly by public recitation, the poems were transmitted for several centuries, until written copies became common. The references below will indicate where full discussion may be found.

In modern schools since the Renaissance Homer has been more read than any other classic Greek author, both because of his importance in the development of European letters and because his peculiar charm is of a sort that attracts young people as well as their teachers. At present Homer is taken up after a very moderate amount of reading in Attic prose, he is continued more or less alongside of other authors in *Gymnasium*, *lycée*, and college; the difficulties of interpretation and the Homeric question are a large topic in university study. Herbart and a very few teachers have maintained that Greek study should begin with Homer, on pedagogical grounds. Evidently that is an error. Would any one maintain that German boys should begin English with Chaucer, or that we should begin German with the *Nibelungenlied*? Homer should rather be postponed till more of Attic Greek has been read, both *Iliad* and *Odyssey* might then be read rapidly and nearly entire. Thus they would make more nearly their proper impression, and give far more pleasure. On the linguistic side at this first reading the comparison with Attic forms, diction, and syntax should aim at full understanding of the poet's meaning, and little more. And the rhythm, a most important element in the poetic form, is commonly quite missed. It is in even, or two-four, time, while English and German imitations, like Longfellow's *Evangeline*, are in triple time. The simplest way to acquire the true movement is to recite a few lines while walking, this leads one naturally to make the two halves of each foot equal, as they should be. For the English lines that is a villainous distortion; for the Greek the true rhythm is far more melodious and expressive. The titles below merely suggest a good line of approach to the works on Homer — a library in themselves.

**HOMERIC EDUCATION** — See GREECE, EDUCATION IN ANCIENT.

**HOMES AND REFUGES FOR CHILDREN.** — See ORPHANS, EDUCATION OF

**HONDURAS, EDUCATION IN** — Honduras has an area of 46,000 square miles with a population, in 1905, of 500,000, or less than eleven inhabitants to a square mile. The vast body of the people are Indians, and of these it is estimated that 90,000 are uncivilized. The republic is governed under a charter proclaimed in 1894 which provides for the election of a president by popular vote for a term of four years and a congress, the members of which are also elected by popular vote, in the ratio of one to every 10,000 inhabitants. The administration of public affairs is intrusted to a council of six ministers, one of whom has general charge of public instruction. The constitution provides for a system of free, secular primary schools, with compulsory attendance

for children seven to fifteen years of age; but by reason of the sparseness of the population, and its racial character, as well as the political upheavals of the country, little advance has been made in the general diffusion of education. The latest official statistics (1909) give the number of primary schools as 660, with about 32,000 pupils; an average attendance is maintained of 75 per cent. For primary education the government expends about \$140,000 (silver) annually.

At the chief town of each of the sixteen departments of the republic there is a school for secondary education (*colegio*) with normal school attached. The government subsidizes these departmental schools and also maintains a Central Institute (secondary) at the capital, Tegucigalpa. Recent efforts have been made to raise the standard of training for teachers and to induce young people to engage in the service by increasing the appropriations for salaries.

For the higher grades of education the following establishments are maintained: At Tegucigalpa, the Central University, with departments of law, medicine, literature, and science. In connection with the university there is a free public library, founded by President Soto in 1880, the College for Women, with courses in modern languages, music, domestic economy, physiology, and hygiene; the National Scientific and Literary Institute; a manual training school for mechanic and decorative arts. There is also a theological seminary and parochial school attached, which is supported by and under the control of the Roman Catholic Church. The National School of Medicine has recently been put upon a firm financial basis, and it is hoped that it may soon recover its former prestige. About 25,000 pesos are annually spent to support students of engineering and other practical professions in the United States, Mexico, and Europe. The increasing demand for engineers has led to preliminary measures looking to provision for their professional training either by the reestablishment of the department of engineering, which was formerly included in the university, or by the organization of an independent school of engineering.

**Honduras, British.** — A crown colony comprising an area of 7562 square miles bordering on the Caribbean Sea. The population numbers about 41,000. The chief town is Belize, with population between 9000 and 10,000. There are forty-one public primary schools in the colony, maintained almost entirely by government grants, which amounted in 1909 to 3714 (\$18,000). The enrollment in these schools was 4417, and the average attendance 3187, or 83 per cent of the enrollment. There are also five private primary schools, of which two have secondary departments, and three private secondary schools. Belize is a center for the local examinations maintained by Cambridge University.

**HONOR SCHOOLS.** — Examinations and courses for degrees in the English universities are divided into two classes, — the pass or ordinary, and the honor school. The requirements for the pass degree are less extensive, and demand less specialized study than those for the degrees in the honor schools. Generally the studies for pass degrees are arranged either in groups or are partly prescribed and partly elective. The studies in the honor schools are narrowly specialized, and demand intensive study in one or two allied fields. The following are the honor schools at Oxford: *litera humaniores*, mathematics, natural science, jurisprudence, modern history, theology, oriental studies, English language and literature, modern European languages. At Cambridge the honor schools are known as Triposes and include classical, economics, historical, law, mathematical, mechanical sciences, natural sciences, moral sciences, medieval and modern languages, oriental languages, and theological. At the Manchester University, to take a modern institution, the honor schools are classics, history, English language and literature, modern languages and literature, philosophy, architecture, economic and political sciences, oriental studies, Celtic studies. The organization of honor courses in the colleges of the United States is very recent. These are discussed in the article on COLLEGE, AMERICAN. The Canadian institutions follow more generally the English custom.

**HOOLE, CHARLES** (1610-1667) — The most important writer on contemporary school practice of the seventeenth century, educated at Wakefield Free School, and graduated from Lincoln College, Oxford (M.A. 1636). He was master of the Rotherham Free School, and afterwards Rector of Great Ponton, Lincolnshire. In 1642, at the outbreak of the Civil War, he went to London and, as Anthony à Wood says, "by the invitation of certain noted citizens he taught a private school there, between Goldsmith's alley in Redcross Street and Maidenhead-Court in Aldersgate Street. By 1651 he had removed his private grammar school to Tokenhouse Garden in Lothbury, not far from the Royal Exchange; where, as in the former school, the generality of the youth were instructed to a miracle." He became later Rector of Stock near Chelmsford in Essex, "where he mostly spent the remainder of his

days with great content to himself and his parishioners." Finally, Wood summarizes him as "a noted royalist and therefore suffered for it in the beginning of the wars, was a good Latinist, Grecian and Hebrician and admirably skilled in classical learning."

Hoole's chief book is entitled: *A New Discovery* [=Description or Disclosing] of the old Art of Teaching Schools, In four small Treatises, concerning 1 *A Petty Schoole*, 2 *The Ushers Duty*, 3 *The Masters Method*, 4 *Scholastick Discipline* — in a Grammar School Shewing how Children in their playing years may Grammatically attain to a firm groundedness in and exercise of the Latine, Greek and Hebrew Tongues. Written about Twenty-three years ago, for the Benefit of Rotherham School where it was first used, and after fourteen years trial by diligent practise in London in many particulars enlarged, and now at last published for the general profit, especially of young Schoole-Masters, etc 1660

At the end of the "Address to All favourers of good learning" Hoole gives a "Note of School Authors most proper for every Form of Scholars in a Grammar School." In one row he places classical authors to be read, and in a parallel row subsidiary authors to be consulted. This he does for each of the forms into which he divides a school. Hoole, in the course of his work, gives the names of between 250 and 300 authors and writers of textbooks allotted out amongst the different forms of the school, and the *New Discovery* is therefore a most important storehouse of school bibliography.

In the *Petty School*, Hoole shows how children should be taught "with delight and profit," pronunciation, spelling, reading. The *Usher's Duty* is chiefly connected with the perfecting of English reading and teaching Lily's Grammar. The *Master's Method* deals with the training of scholars in Grammar, Authors, and Exercises; Greek, Latin, and Hebrew. The *Petty School* is a preliminary school, the usher deals with Forms I, II, III and the Master's work begins in Form IV.

Hoole deserves credit for laying emphasis on the earliest teaching of the child. He says: "The Petty [*i. e.* French *petit*] school is the place where indeed the first principles of all religion and learning ought to be taught, and therefore rather deserveth that more encouragement should be given to the teachers of it than that it should be left as a work for poor women or others, whose necessities compel them to undertake it as a mere shelter from beggary." Hence he appeals for the appointment of well qualified teachers for the *Petty School*, and the endowment of such posts with adequate funds, especially praising Bathurst and Gouge for their efforts in this direction. He considers forty children as many as any one teacher ought to have in one class. In the section entitled *Scholastic Discipline* Hoole deals with the Founding of a Grammar School, and appeals for provision of further schools and masters.

Besides the *New Discovery*, Hoole wrote: (1) *An Easie Entrance to the Latine Tongue*. 1649 (2) *Terminationes et Exempla Declinationum et Conjugationum*. 1650 and 1659. (3) *Propria Quae Maribus, Quae Genus and As in Praesenti, Englished and Explained*. 1650. (4) *The Latine Grammar Fitted for the Use of Schools*. 1651 (317 pp.) (5) *Ἡ ΚΑΙΝΗ ΔΙΑΘΗΚΗ. Novum Testamentum. Huic editioni omnia difficultiorum Vocabulorum Themata, quae in Georgii Pasoris Lexicon Grammaticae resolvuntur, in margine apposuit Carolus Hoole. In eorum scilicet gratiam, qui prima Graecae Linguae tyrocinia faciunt*. 1653 (6) A translation of Maturinus Corderius's *School-Colloquies*. 1657 (7) *Vocabularium Parvum Anglo-Latinum, In usum Puerulorum, qui prima Latinae Linguae Tyrocinia faciunt*. 1657 (8) *Sentences for children, English and Latin from Leonard Culman*. 1658. (9) A translation of Comenius' *Orbis Sensualium Pictus*. 1659. (10) A translation of Cato's *disticha de Moribus, Dicta insignia Septem Sapientum Graeciae, Mimi Publiani, sive Senecae Proverbia, Anglo-Latina*. 1659 (This contains a valuable Preface by Hoole on his Methods.) (11) *Children's Talk, English and Latine*. 1659. (12) *The Common Rudiments of Latine Grammar Usually Taught in all Schools*. 1659. (166 pp including Index) (13) *Examinatio Grammaticae Latinae in usum Scholarum adornatae*. 1660. (14) *A Century of Epistles English and Latine; selected out of the most used School-Authors — viz. Tullii, Plinii, and Textor*. By imitating of which children may readily get a proper style for writing letters. 1660 (15) *P. Terenti Comoedia Sex Anglo-Latinae*. Edited by Hoole, 1663 (16) *Aesop's Fables English and Latin*. 1700 F. W.

#### HOPE COLLEGE, HOLLAND, MICH. —

Founded in 1851 as Pioneer School, reorganized as Holland Academy in 1857, and incorporated as Hope College in 1866, this institution is co-educational and is under the auspices of the Reformed Church in America. In addition to the college a preparatory school and a school of music are maintained. The requirements for entrance are about fifteen units. The college courses are arranged in classical, philosophical, modern language, and natural science groups, and all lead to the A.B. degree. There are twenty members on the instructing staff. The total enrollment in 1910-11 was 388.

**HOPKINS BEQUEST AND THE HOPKINS GRAMMAR SCHOOL** — The fund was established by the will of Edward Hopkins, a London merchant who emigrated to Hartford in 1638, and was many times governor of Connecticut. Subsequently returning, however, to England, he died there in 1658. After making other bequests, he left the residue of his New England estate — besides £500 to be delivered upon the death of his widow — “to give some encouragement in those foreign plantations for the breeding up of hopeful youths in a way of learning, both at the grammar school and college”, two residents of each Connecticut colony were named to execute the trust. After some hindrance the trustees in 1664 gave £400 for the grammar school at Hartford, and agreed to divide the remainder equally between the grammar schools at New Haven and Hadley, Mass., the latter being obligated, however, to give to Harvard College the sum of £100. Eventually, New Haven received £412 and Hadley £308. When the widow died in 1699, none of the original trustees surviving, then successors applied for the £500 bequest, but were told that the estate did not suffice to pay it. In the hesitation to enter upon a doubtful suit at law in a distant court, nothing was done. In 1708 the Society for the Propagation of the Gospel (*q v*), learning of the failure of the bequest, moved in Chancery that it be assigned to the Society. Whereupon friends of Harvard College moved vigorously in the matter and recovered nearly £800, principal and interest, of which sum the master in Chancery awarded three fourths to Harvard and one fourth to the Cambridge Grammar School. It does not now appear how this direction of the fund was justified.

The bequest so apportioned has been used in the main as directed. New Haven has utilized her portion most successfully. The Hopkins Grammar School, organized in 1668, has maintained an unbroken succession under the original trust, and has proved a most important preparatory school to Yale almost from the foundation of the latter. Hadley, Hartford, and Cambridge have not maintained separate foundations. The first of these has merged its remaining colonial grants and donations in the town high school, the two latter maintain from similar funds classical masters in their respective high schools. At Cambridge he is called the Hopkins classical master.

**HOPKINS, MARK** (1802-1887). — Fourth president of Williams College, born at Stockbridge, Mass., Feb. 4, 1802. He was instructed by private tutors and at the Clinton Academy, and was graduated from Williams College in 1824. Five years later he completed the course of instruction at the Berkshire Medical School. He was for several years instructor in private schools at Stockbridge and Richmond. For six years (1830 to 1836) he was a professor, and for thirty-six years he was president of Williams College. Under his presidency the course of instruction was broadened and the system of discipline modified. Physiology and other sciences were added to the course, and he developed the theory that “the college that is best is that in which there is the least government.” He made the personal influence of the teaching staff the chief factor in the government of the college. He was active in promoting the cause of education in mission fields, and gave three courses of lectures on moral science before the Lowell Institute (1844, 1860, 1861). In addition to his numerous sermons and addresses on education, he published *Lectures on Moral Science* (1862), *Christian Ethics* (1869), *An Outline Study of Man* (1873), and *Teachings and Counsels* (1884). He died at Williamstown, Mass., on June 17, 1887, having continued his connection with the college as lecturer on mental and moral philosophy after he resigned the presidency.

**HORMAN, WILLIAM** (d. 1535). — English schoolmaster, born at Salisbury and educated at Winchester. He may have studied at Cambridge, and was fellow of New College, Oxford, when he became master at Eton in 1487, in 1494 he became master of Winchester until 1502, when he became fellow and later vice-provost of Eton. Horman was the author of many works in the fields of history, theology, and grammar. His best known work was the *Vulgaria*, published by Pynson in 1519, a collection of sentences in English and Latin arranged according to subjects, e.g., *de pietate, de impietate, de exercitamentis et ludis*, etc. The work presents an interesting picture of school life as seen by one who knew the two best schools of his day intimately. In the *Antibussicon* (1521) Horman came to the defense of his friend, William Lily (*q v*), whose method

of teaching Latin had been attacked by Robert Whyttington.

**HORNBOOK.** — A device for teaching the alphabet and the first reading lessons to beginners. It consisted of a flat board with a handle, and on this was pasted a sheet of paper containing the letters of the alphabet, the vowels, combinations of vowels and consonants (*ab, eb, ib,* etc.), the Benediction (In the Name of the Father, and of the Son, and of the Holy Ghost Amen), the Lord's Prayer, and sometimes the Roman numerals. Over this was placed a thin sheet of transparent horn, which gives the name to the device, held down by narrow strips of some thin metal and nails. The handles were generally pierced with a hole by which the hornbook was fastened on the girdles or round the necks of the scholars. The backs of the hornbooks, such as were used in noble families, were sometimes covered with leather embossed with a picture of St. George and the Dragon, or Charles I. mounted on a horse, or with silver or gold filigree work. When the hornbooks came into use cannot now be traced, but they were certainly known at the beginning of the sixteenth century. In a manuscript of Sacrobosco, c. 1442, a teacher is represented holding in his hand a board shaped like the hornbook, on which the Roman numerals up to nine are written (see Smith, *Rara Arithmetica*, Boston, 1908). The hornbook, containing only the alphabet, appears in an illustration in Reisch's *Margarita Philosophica*, issued in 1503. By the end of the sixteenth century the use of the hornbook is referred to as a common practice in English literature. And so it continued to be to the end of the eighteenth century, for in 1799 a large English dealer in hornbooks found that orders for them came to a stop. In America the use of the hornbook was as widespread as in England, and declined at about the same time, the end of the eighteenth century. The hornbook of the English and American type is not found in Europe, although similar shaped alphabet boards without the horn were used, as e.g. in Holland (*AB boordje*), Germany (*ABC Tabella*), France (*tablette, carte, La Croix de par Dieu*), Italy (*un abbici, centuruola*).

Since the letters of the alphabet in hornbooks and primers were sometimes preceded by a cross, the first line and frequently the whole alphabet was called criss-cross (Christ's cross) row. It is known that the hornbook was sometimes made in the shape of a cross, although examples are difficult to find.

Gingerbread hornbooks were familiar in the eighteenth century, the pupil being allowed as a reward to eat the letter which he learned.

Derivatives of the hornbook were the cardboard and wooden battledores on which the letters of the alphabet were printed. In spite of the great vogue of hornbooks, very few still remain, and their value, once 1d or 2d, has now risen to \$100 or \$150.

See PRIMER.

TUER, A. W. *History of the Hornbook* (London, 1897.)

**HORNE, THOMAS** (1610-1654) — Headmaster of Eton College, 1648-1654. He was educated at Magdalen Hall, Oxford, 1624-1628. Between leaving Oxford and becoming headmaster of Eton, Horne had taught a private school (c. 1633) in London, had been master of the Free School at Leicester for two years and headmaster of Tonbridge School from 1638 to 1848. His son William became headmaster of Harrow. Horne was a translator of the *Janua Linguarum* — as drawn up by William Bathe or Bataeus (1564-1614), head of the Irish College of Jesuits at Salamanca. The book therefore is to be distinguished from the *Janua Linguarum* of Comenius (*qr*), who borrowed part of the idea from the *Salamanca Janua*. Horne's editorial work on the *Salamanca Janua* is more careful than that of John Harmar (*qr*). He revised the English of the former version of William Welde and John Harmar, edited the Latin text of the *Janua*, altered the order of the words, and added marginal notes. It is interesting to note that Thomas Horne was the last translator into English of the *Salamanca Janua Linguarum* (1645) and the first translator of Comenius' *Janua Linguarum* (said to have been published as early as 1634). In 1641, while headmaster of Tonbridge School, Horne published *ἡεραγωγία — sive Manuductio in Aedem Palladis*. This book discusses the most valuable method of reading good authors. It is one of the best works of the period for showing contemporary school aims in the teaching of classics. Horne realizes the place of observation and comparison of words and sentences, as well as phrases, and epithets, and the mental discipline involved in the attention to the minutiae, of composition, and insists, as Vives and Ascham had done, on entries in paper books of all that has been observed in the reading of authors, and he gives a full account of imitation in writing. (See COMMONPLACE BOOKS.) Horne also wrote *Rhetoricae Compendium (Latino-anglicé)*, 1651. F. W.

**HORTICULTURE, EDUCATION IN.** — In North America, a group of subjects has been assembled in colleges of agriculture under the general name of Horticulture, including fruit-growing or pomology, flower-growing or floriculture, vegetable-growing or olericulture, and also ornamental gardening and the general glass-house and nursery subjects. It is not a homogeneous group, but it has so happened that persons have been trained to handle it as a coordinate to the group of general agriculture. The group of general agriculture has included the main or prevailing farm organization, the raising of staple foodstuffs and the rearing of animals, whereas horticulture has comprised many of the adjunct and amateur and semi-urban phases of farm life. The old pedagogical group of agriculture is being divided into its component parts, and in the most advanced of the colleges of agriculture, the word "agriculture" is no longer used as a name for courses, animal husbandry, farm mechanics, dairying, soil subjects, and others, have been separated out of it, and there is now a tendency to separate the farm-crops part into its units. Similarly, horticulture is in the process of division. In some institutions the three main parts are now separated or in active process of separation. Whether these and other parts of the subjects shall be treated as separate entities and be coordinated under one administrative unit known as horticulture, is mostly an institutional question, but there can be no doubt that now or in the near future the parts must be handled by different specialists. The horticultural industries have now become much differentiated and often highly specialized, and they frequently comprise entire farming schemes, and this calls for a very free handling of the subjects in the colleges.

In this country horticulture has developed as a college subject rather than as a common school or training school subject. Only very recently have we begun with much hope of success to found special separate horticultural schools on the plan of European establishments. The earliest special developments of horticulture in the colleges of agriculture appear to have been in Michigan under Tracy, Garfield, and successors (W. W. Tracy was assistant professor of botany and horticulture in the Michigan Agricultural College in 1867, and full professor of horticulture in 1869), New York (1874) and Ohio under Lazenby, Iowa under Budd, 1876. Probably the first full professorship in horticulture in a university, with no other name in the title, was that established at Cornell in 1888. Probably the first experiment station to employ a "horticulturist" was the New York Agricultural Experiment Station, at Geneva, 1882. At present, horticulture is represented by a department or in the title of an officer in practically all the American colleges of agriculture, and also in experiment stations, and the equipment in many cases is very large.

In most early professorships horticulture was associated with botany, forestry, or landscape gardening. As a separate subject or chair, it was often an offshoot of botany. Although it touches affairs at every point, horticulture is primarily a biological subject, and it must always have the closest associations with botany.

*The Field of Horticultural Education* — In the specialization in colleges of agriculture, some of the subjects that formerly were included in horticulture are segregated to separate departments. This is coming to be true of plant-breeding and of some of the other applications of botany. But the real field of the horticulture group still remains, sufficient in range and variety to attract the best effort of the very best men. In the applications, the colleges of agriculture must assuredly teach along the lines of public needs. The public needs in this field are well expressed in the kinds of horticultural societies that are now most prominent. The vigorous horticultural societies are of four kinds — pomological, floricultural, market-garden, and nursery business. These represent four great horticultural trades or occupations, persons who are expert in one of these occupations usually are not expert in others. Every highly developed horticultural department should have at least these divisions. If it is not desirable, in any commonwealth, to have a separate nursery sub-department, it will still be necessary to teach something of nursery practice as an underlying and co-ordinating part of all good horticultural work.

Each of these divisions must be in charge of a man who is expert in the trade, as well as thoroughly grounded in the science and philosophy of the occupation. The laboratory work should be abundant, and it should cover the whole theory and process of the given art. In the pomological division there should be a laboratory of, say, thirty acres of actual orchards, in which all phases of the work, from start to finish, may be in natural operation, and if these phases cannot be taught at the time of year when the students are in the habit of coming to college, the time of coming should be changed, for the seasons, and the operations that follow the seasons cannot be changed to suit a traditional college year. Similarly, in the other lines there must be ample areas that are used as teaching laboratories, — actual nurseries, actual glass houses of practicable extent, actual garden farms in operation. All the work, if it is to be of college grade, must be projected on a background of sufficient training in the natural sciences and the essential arts.

To meet the needs of rural civilization, it is essential that we build large and in such a way that the future necessities will expand our scheme rather than break it. In material equipment there must be (1) land, (2) a large area under glass, (3) orchards, nurseries, gardens, (4) buildings containing special scientific laboratories, libraries, classrooms, and the like, (5) museums.

The museums should be active teaching equipments. One museum might well contain cross-sections of all the kinds of greenhouses and all greenhouse appliances; another, all the spraying machines, and these machines might be used on occasion, another, the hand implements of horticulture, another, all the horticultural pottery, another, the horticultural products, and others will be needed. In addition, there should be living museums, — one containing the trees and shrubs (an arboretum), another containing the varieties of fruits, another containing the perennial and other herbs. There should be some one place in every state where all these various things are preserved and on exhibition for the information of students and the people.

There is another class of subjects that is yet undeveloped in horticultural departments. The dairy departments of agricultural colleges are largely manufacturing enterprises, they manufacture butter and cheese and other milk products. They cover a definite set of problems, and this is one reason why they are developing rapidly. There are also horticultural manufactures, — canning, preserving, evaporating of vegetables and fruits, the making of jellies and juices and other secondary products, — some or all of which should be investigated and taught by the colleges of agriculture. The utilization of the waste products of fruit growing and vegetable growing has scarcely begun to develop in this country, and the manufacture of the staple horticultural products is not yet taught.

*As a School Subject* — In the public schools horticulture is not likely to be taught, in general, as a separate subject or class. Pieces of agriculture are put together into some kind of educational plan or sequence, and some of these pieces are derived from horticultural subjects. In particular schools fruit growing or flower growing or other applications may be introduced to meet local demands. Gardening may be made a most useful adjunct to school work, but its purpose in most cases — particularly in the formal school garden — is to provide a base for the development of nature study and for general training rather than primarily to teach garden culture as such. The influence of plants and of planting on children is not yet sufficiently understood. Horticultural subjects will be increasingly important as means of putting the pupil in touch with the situations in life.

There is undoubtedly to be a demand for special training schools and trade schools of horticulture. Probably some of them will soon be differentiated as floricultural or other technical schools. The fact that so much of the horticultural work is manual and is accomplished under glass, makes it very useful as a training subject. In the horticultural industries there will probably be an increasing field for women, and horticultural schools for women (one of which has recently been estab-

lished in the United States) may be expected to arise near many of the populous centers.

*Amateur Gardening* — Gardening is the great outlet of the amateur. No other phase of land work offers such variety, covers so completely the progress of the seasons, is adaptable to so many situations and climates, or allows such complete expression of personality. Therefore the teaching of amateur gardening is of the greatest importance both for country and town. In the colleges of agriculture the commercial aspects of horticulture are chiefly emphasized, but the amateur side may be expected to become prominent as the country matures. A different order of abilities is required in the teacher of amateur gardening from that demanded in the handling of education for the great commercial specialties, and we cannot expect the subject to develop strongly in the colleges until special teachers are provided. These teachers must be highly skilled in the feeling for plants and well trained in the skill of plant growing. It is probable that the special schools of horticulture, that are very strong on the manual side, will largely meet these needs, particularly for town lot and suburban gardening.

*Literature* — There is a large American literature of horticulture, but there are no school textbooks among these writings (if we exclude school-gardening texts). All the texts on agriculture contain more or less horticulture, and horticulture is properly a part of agriculture. There are yet (1911) no books of college grade in the generalized horticultural field, that are prepared expressly as class texts, but many treatises on particular subjects are used as class books and reference books. Textbooks in fruit-growing, vegetable gardening, floriculture, and the like, will undoubtedly soon appear. They are particularly needed for college work. Manuals of various kinds will be helpful in the training schools. L. H. B.

**Horticultural Education in Europe** differs from similar work in America most conspicuously in the fact that it is never given as a part of a college or university course. Frequently there are given special courses of instruction, essentially like those provided in the several "short courses" of American agricultural colleges. The typical plan, however, is that of a special or "continuation" school, in which attention is focused directly upon the technical training, little or no attention being given to the questions or materials of general education.

One of the best of these institutions is the Horticultural Institute (*Königliches Gärtnerei-Lehranstalt*) at Dahlem, in the suburbs of Berlin. This institution is thoroughly typical, and a brief description of its organization will give a fair idea of how such work is conducted in continental countries. The institute owns a tract of approximately twenty acres of very excellent garden land inclosed by a high fence on all sides. Within the privacy of this in-

closure live the director and a few workmen who are directly responsible for the care of the place. The plant consists further of a large classroom building, a small greenhouse equipment, and a small experimental laboratory. No students live in the institute buildings, though in many other places the residence of students is an essential part of the plan. About the buildings is a small tract laid off in ornamental gardens, containing on a small scale the usual features of an arboretum and nursery. A large collection of plants is made unnecessary through the close proximity of the unrivaled Berlin Botanic Gardens. There are extensive plantations of dwarf and trained fruit trees and of small fruits. Garden vegetables are cultivated on a smaller scale. The course of instruction covers two years, and is divided into three principal vocational lines (1) garden art (landscape gardening), (2) fruit culture, (3) plant culture. Instruction is given chiefly by lectures, with occasional demonstrations and practicums. There is less field work, either required or voluntary, than in similar courses in American agricultural colleges. The reason for this lies largely in the fact that applicants for admission are required to present certificates showing one year of voluntary military service and three years of practical field experience. The work is designed, therefore, to meet the needs of men who have already entered upon their professions and who have a fairly substantial groundwork of experience upon which to build their theoretical education.

A number of the European schools are founded by particular societies or by local municipalities, in order to assist special industries. There is, for instance, a school for the canning industry in Brunswick, a district where large quantities of fruit and vegetables are canned, there is a school especially adapted to the needs of vine growers at Geissenheim, in the wine district; and so on. Similar local schools, some highly specialized and some more general in their scope, are to be found in Switzerland and Austria. The National School of Horticulture at Versailles is the most important one in France. In England there are several horticultural schools, mostly of a strictly local nature, the one at Wisley being perhaps the most famous. In this connection, however, the work at Kew should never be forgotten. Here many of the best gardeners have received their training. The apprentice system is, however, the most popular method of training gardeners in England, and is in general the typical method of horticultural education in that country.

**HOSPITAL ECONOMICS.** — See NURSES, EDUCATION OF.

**HOSPITAL SCHOOLS.** — A hospital means primarily a guesthouse, and may be defined as an endowed inn or public house for the reception of guests gratis, whether they were travelers, poor, aged, children (especially orphans or foundlings), or sick. Hospitals seem to have been unknown to the ancients, Greek or Roman, in classical times. The Jews dispute their invention with the Eastern Christians, but the balance of evidence is in favor of the latter. The earliest hospital known to history appears in the middle of the fourth century A D, when Eustathius appointed a superintendent of the Hospital (*xenodocheron* or *ptochotropheion*) for the poor at Sebaste in Pontus. Epiphanius speaks of it already as a custom for bishops to maintain such institutions (*Hieres*, 75, c 1). One of the first acts of Basil the Great (*qv*) on becoming Bishop of Casarea was to include hospitals for travelers, the poor and the sick in the institutions which he founded. Julian the Apostate directed the establishment of state hospitals as rivals to those of the Christians. The Council of Chalcedon in 451 placed the clergy in charge of hospitals on the same footing as churches, and Justinian (*Codex* I, 42, 46) deals with the five classes of hospitals under the heading of "bishops and clergy."

From the first hospitals became connected with education. Among the earliest hospitals were orphanages and founding hospitals, owing to the prevalent pagan practice of exposing infants and deserting children. Constantine the Great himself established an orphanage at Constantinople, and formally sanctioned the gift of endowments to them. The warden of orphans (*orphanatropus*), a priest, was a high official. The orphanage became the song school (*Scola Cantorum*), and in Greek rituals the term "orphans" was used as equivalent to choir boys.

The earliest mention of hospitals in England is found in a letter written by Alcuin (*qv*) to his old pupil Eanbald II, in which he recommends to the newly made archbishop the establishment of guesthouses (*xenodocheia*), that is, hospitals (*hospitalia*), at the same time that he discusses the organization of the school. St. Peter's, afterwards called St. Leonard's Hospital, which has been imputed to King Athelstan, c 932, may well have been founded by Eanbald II on Alcuin's advice and augmented by Athelstan. By 1280 this hospital was used partly as a foundling hospital "ministering to the poor and sick and to infants exposed there." There were twenty-three boys in the orphanage under charge of a woman, and they, together with no less than thirty choristers, were educated, two masters, one of grammar and the other of song, being maintained to teach them. The dean and chapter of York attempted to close the school in 1340 because the master was unlicensed; but the King upheld the school as a royal foundation, and "free from all ordinary jurisdiction." The two schools were still being

maintained in the Hospital in 1535, and only ceased on the dissolution of the hospital, when the Cathedral Grammar School was put on a more substantial basis

At the Hospital of St. Cross, near Winchester, founded in 1132 by Bishop Henry of Blois, thirteen poor men were maintained, and dinners were provided for a hundred other poor. In evidence given in 1373 it appeared that among the hundred poor men had always been included "thirteen of the poorer scholars of the High Grammar School of the City of Winchester." There were also attached to the hospital four hired priests, and, probably a later addition, "thirteen poor secular clerks' scholars," and seven poor grammar (*litterati*) boys, two of whom were called choristers and the rest served in the church, "and the services finished, attended school in the same hospital." In the same manner three scholars of Durham school received food, drink, and beds in St. Cuthbert's Almshouse at Durham (1190). In the case of the Hospital of St. Katharine by the Tower, founded in 1147 for thirteen poor women, six scholars were added in 1272 to act as choristers in the Hospital chapel or church. The six poor scholars are now represented by two elementary schools, one for boys and one for girls, in Regent's Park, London, since 1826. At Norwich Bishop Suffeld founded in 1249 what is now known as the Great Hospital, originally God's House or St. Giles' Hospital, intended for the infirm, under a master, four chaplains, and four sisters. In addition to thirteen poor people who were daily to receive dinner, there were also seven poor scholars who were to be named by the master of the grammar school. By 1430 the seven poor scholars had become choristers in the Hospital church. The Hospital was dissolved by Henry VIII, who, however, provided for its reconstitution by his will, and in addition to the Hospital a grammar school was to be established with a "scolemaister" and usher "to teche frely without any reward other than their stypends of £10 and £6 13 4. and convent houses." At Bridgewater in Somersetshire the rectory of Wembdon was appropriated in 1285 to the Hospital of St. John, founded before the reign of King John, for maintaining six more chaplains and "thirteen poor scholars of ability to learn grammar, who should be maintained in the Hospital but attend the school of the town daily." Seven other poor scholars of the school were to receive daily pittance from the hospital kitchen, pottage, etc. These boys were still being kept in this way in 1535, the date of the *Valor Ecclesiasticus*. Precisely the same arrangement was made at York, where St. Mary's Abbey kept a boarding school for fifty boys who attended the cathedral grammar school.

Instances proved by contemporary documents of the definite endowment of university education in connection with a hospital are that of the Englishman Joyce or Joicey at Paris,

in St. Mary's Hospital, a room in it with eighteen beds being set aside and stipends provided for eighteen scholars or clerks. (See COLLEGE.) This arrangement was imitated in the first university college in England, the House of the Valley Scholars, founded at Salisbury, in 1262, by the Bishop Giles of Bridgeport, in connection with and apparently in the precinct of the Hospital of St. Nicholas there. (See Rashdall, *Universities of Europe*, Vol II, p. 766.) So Merton, the earliest college at Oxford, was in connection with a hospital for the poor at Basingstoke, Hampshire, to which the scholars might themselves retire when old or incapacitated. In like manner St. Bartholomew's Hospital at Oxford was annexed to Oriel College in 1325, and St. Julian's Hospital, Southampton, to Queen's College in 1340. The colleges maintained the poor, but took all surplus to themselves. The earliest Cambridge college was originally planted in St. John's Hospital there in 1280. But the brethren of St. John's were "regulars," and could not get on with the secular scholars, so in 1286 the scholars were removed to what is still called Peterhouse. St. John's Hospital was itself dissolved under a Papal Bull and converted into the present St. John's College in 1504, just as St. John's Hospital at Oxford had been dissolved by the Pope and converted into the present Magdalen College, Oxford, in 1480. Both were following many precedents in connecting scholars with hospitals, though not of actual dissolution and conversion of one into the other.

How much neglect and malversation there were in the management of hospitals may be seen from the decree, *Quia Contingit*, of the Council of Vienne (1310-1311), which appears in the *Corpus Juris Canonici* (Clement III, tit. XI, 2) under the misleading title of "Religious houses and their subjection to bishops." Most hospitals were then in the hands, not of secular clergy, but of the religious or regulars, particularly the Augustinian canons. By this decree the Ordinary is given power to investigate and reform hospitals, which were no longer to be conferred as ecclesiastical benefices. An exception was made in favor of the military orders, the Knights of St. John, and the religious, who were only to be subject to their own superiors. In England the first Parliament of Henry V at Leicester in 1414 investigated similar conditions and empowered the ordinaries to hold inquiries and reform the hospitals. There was a tendency more and more in the fifteenth century, with the disappearance of leprosy, to convert the funds of hospitals to other uses; many hospitals became almshouses, and many were connected with educational purposes. Thus Wilham de la Pole, Earl of Suffolk, founded an almshouse, in which he also planted a grammar school, at Ewelme, in Oxfordshire (the license being granted in 1437 and the foundation statutes made not earlier than 1448). The "Howse of almesse" or "Goddiss Howse"

was to consist of two priests and thirteen poor men; one of the priests was to be "apte and able to techyng of gramer, to whose office it shall longe and pertayne diligently to teche and informe childer in the faculte of gramer." The children of the lordship of Ewelme were to be admitted to the school without tuition. The Hospital remains almost intact, but the school has been sadly modernized and mauled to make it an elementary school and so save a few pounds in rates. This institution is of great historical importance, as the Earl of Suffolk was one of Henry VI's main agents and advisers in the foundation of Eton, which probably owed its being in part as almshouse to his influence and example. To the same influence may perhaps be attributed the school of St. Anthony's Hospital, in Threadneedle Street, for about a century and a half one of the most famous of London schools. In 1441 the rectory of St. Benet Fink was appropriated to the Hospital founded in 1253 for sufferers from St. Anthony's Fire, and later (1441) continued as a hospital for the poor merely. The endowment of the rectory was intended for the maintenance of "a master of fit Informers (*Informator*) in the faculty of grammar to keep a grammar school in the precinct of the Hospital or some fit house close by to teach, instruct and inform freely (*gratis*) all boys and others whatsoever wishing to learn and become scholars (*scholasticare*)."

It was a school precisely on the same lines as Eton (*q v*). A song school had been already established in the preceding year for the choristers of the hospital. New statutes were made for the hospital in 1446, and in 1447 the hospital was brought into connection with Oriel College, Oxford, by maintaining scholars studying there. In 1475 the hospital was annexed to St. George's, Windsor, and suffered thereby, for the canons, wishing to increase the surplus payable to themselves, cut down the salaries of the masters. The school, however, flourished in numbers, and according to Stow, who was probably a boy there, St. Anthony's Hospital "commonly presented the best boys and had the prize in those days" at the disputations held in St. Bartholomew's Midy on St. Bartholomew's eve (August 23). A regular feud existed between St. Anthony's boys and those of St. Paul's, the former calling the latter pigeons, because of the pigeons inhabiting then as now the churchyard, and the Paulines calling the Antonies "pigs," because all stray pigs were the perquisites of the hospital. In 1589 the school had sunk to little more than a parish school, but it continued till the Fire of London in 1666, after which it perished and was not rebuilt. The endowment was swallowed by the dean and chapter of Windsor. At about the same time the greatest of London Hospitals, then as now, St. Bartholomew's, was connected with education. In 1444 John Stafford, chaplain and citizen of London, left property to the

master of the Hospital, including among other things "for the increase of the clergy and of divine service" £1 13 4 a year more "for the diligent instruction of boys in grammar and song." This school has been left unnoticed by historians of the hospital, although it may well have contributed to the establishment of the grammar and song schools in Christ's Hospital, when a scheme was made for the four great London hospitals at the end of Edward VI's reign. While in the fifteenth century, far from a period of decadence in learning, schools were added to hospitals, in the sixteenth hospitals were boldly annexed and converted to educational uses, *e g* the Hospitals of St. John at Oxford and Cambridge. In 1501 John Stansbridge (*q v*) became master of the Hospital of St. John the Baptist at Banbury, which was treated as a school and the mastership as a schoolmastership rather than as a hospital and ecclesiastical preferment. The school seems to have ceased in 1558.

The *Valor Ecclesiasticus* of 1535 revealed the extent to which the hospitals were mismanaged. In one after another there were only one or two poor, and the master took nearly the whole of the revenues to his own use, and where there were none he took the whole. A large number of hospitals were still in the hands of the regulars. The acts for the dissolution of monasteries also included hospitals. So fell the Hospitals of St. Bartholomew and St. Thomas in London and Southwark, only to rise again in enlarged form.

The greatest of all hospital schools was that of Christ's Hospital, London, founded in 1553. This was the only educational institution really founded by Edward VI in the sense of creating a new school where none had existed before, and it was not founded as a school or for education primarily, nor was its site nor a penny of endowment given by Edward VI. His contribution to it consisted of a piece of parchment and some confiscated church linen, and the name of "the Hospital of Christ, Bridewell and St. Thomas, the Apostle." Christ's Hospital was the deserted monastery of the Grey Friars, the Franciscans or Friars Minor, one of the largest churches in the city next to St. Paul's. It was acquired by the city from Henry VIII in 1547, and in 1550 the Lord Mayor, Sir Richard Dobbs, brought before the Court of Aldermen a plan for the suppression of vagabondage and poverty by taking "out of the streets fatherless children and other poor men's children that were not able to keep them to the late dissolved house of the Grey Friars, which they decided to be a Hospital for them." In 1552 the Grey Friars was prepared as Christ's Hospital by the subscriptions and contributions of citizens and the common council. This was part of a general scheme to deal with every class of destitute poor, and the charter included the "Royal Hospitals" of Christ, Bridewell, and St. Thomas," which with

St Bartholomew's, which the city already had, made up the "Four Royal Hospitals." In November, 1552, 380 children were admitted into it. It appears from the evidence of a contemporary, an official of the Hospital, that it was a Foundling and Orphan Hospital for "gutter" children, and this is confirmed by the names on the admission book, which, however, only begins in 1556. In 1639 it was ordered that no child be admitted under three, but even as late as 1653 out of 218 children 120 were under four. In 1677 a rule was made excluding children under seven. Education is so far mentioned in this charter in that it says that one of its objects is that "neither children yet being in their infancy shall lack good education and instruction nor when they shall attain riper years shall be without honest callings and occupations, nor that the sick or diseased when returned to health may remain idle and lazy vagabonds but in like manner may be placed and compelled to labour." Grafton, the printer, however, who took a principal part in the establishment of the Hospital, and others were fully convinced of the necessity of educating their foundlings and orphans. They put in two "scholerausters for the petties in ABC" at £2 13 4 a year, 13s 4d more than the barber and not half what the porters got, a "teacher to wrighte" was paid £3 6 8 a year, a teacher of pricksong £2 13 4, a "scholerauster for musike" £2 13 4. But they also provided for a "Grammar Schoole mayster" at £15 a year and a "Grammar Usher" at £10 a year. Grafton was put into the Fleet prison in Queen Mary's reign because he allowed "the children to learn the English primer instead of the Latin abscies [A B C's]," the latter having the Paternoster and prayers in Latin. At first the children were clothed in russet (brownish red cotton), but at Easter, 1553, they appeared in the blue cloth which has made the "Blue coat boy" so famous throughout the world. But whereas of later years they have been noted for going about bareheaded, they originally had red caps. Queen Mary wished to suppress the Hospital and put back the Friars, but the Spanish Friars themselves advised against it. Only one endowment was given in her reign, but in Queen Elizabeth's subscriptions, bequests, and legacies poured in, and by Camden's time, about 1590, 600 children and 1240 pensioners were maintained. But of these not more than 200 were in the Grammar School, and only those who attained the two highest forms, "Deputy-Grecians" and "Grecians," were retained after the age of sixteen. In 1673 the above boys were increased in number by the Mathematical School of forty boys founded by King Charles II to prepare them for sea—one of the earliest institutions of its kind in recognizing that a classical education was not good for all boys. In 1774 the girls were moved to a separate establishment at Hertford, where a nursery, afterwards trans-

formed into a preparatory school had long been established. The number was then 800, of whom about 200 boys under twelve were at Hertford. Under a scheme of the Charity Commissioner in 1890 the boys' school was removed in 1902 to Horsham to an ample site and splendid buildings. For about 150 years before the scheme the Hospital was practically governed by those rich enough to pay £500 for the privilege of being governors and having the patronage of appointing the boys, with the result that the class of boy had been more and more raised in wealth and the class for whom it was intended was no longer found. A third of the boys are now admitted by competitive examination from elementary schools, and to that extent the original class has now been restored (See GRAMMAR SCHOOL, PUBLIC SCHOOLS).

The Blue Coat School, as it was commonly called, became a model for other foundations of the same sort, though none of them attained the size or fame or educational advancement of Christ's Hospital. The earliest of these was Emanuel Hospital, Westminster, in 1594, the Charterhouse, which combined an almshouse for decayed gentlemen with a grammar school in the old Carthusian Monastery of London in 1611, but this catered more for the lower classes like Christ's Hospital; the Blue Coat Hospital, in the old St. John's Hospital, Exeter, followed in 1632, the Green Coat Hospital, Westminster, 1633, Chetham's Hospital, Manchester, 1651, the Grey Coat Hospital for girls, Westminster, 1706. Scotland also in George Heriot's Hospital in Edinburgh, 1628 (see HERIOT, GEORGE), Gordon's Hospital, Aberdeen, 1732 (see GORDON, ROBERT), and diverse others, including Morgan's Hospital at Dundee, building in 1867, followed the example. (See also HUTCHESON EDUCATIONAL TRUST.) A new crop on a smaller scale sprang from the Charity School (*qv*) movement in 1705, of which one of the largest remaining is the Blue Coat School at Sheffield. These later ones aimed rather at training children for domestic service, and gave no more than a purely elementary education, and were strongly condemned by the Schools Inquiry Commission in 1867 as wasting large funds for no appreciable educational result or advancement of the children. Many of them, like Emanuel Hospital, Westminster, now the Westminster City School, have been turned into higher grade or technical day schools, meeting a much-felt want in large towns for commercial and technical education of the poorer boys. The connection of hospitals with general education has now practically ceased, except in regard to medical education and training, which are treated under a separate article (See MEDICAL EDUCATION.) **HOUSEHOLD ARTS IN EDUCATION.** —  
**Terminology** — Various terms have been used to indicate the content of this broad subject, to signify its connection with the home, and to indicate the fact that science, fine art, and the technical arts are fundamental. The terms most in vogue at present are either home economics, household science and arts, household science, or household arts. The English Board of Education has introduced the term "housecraft" (1911). The term "economics" is perpetuated in the American Home Economics Association, and is used in a number of institutions. The term "household science and arts" would seem to include everything required, but it is inconveniently long. Household science does not include the art application. Household arts, on the other hand, while it seems to emphasize the practical or applied side, also implies a scientific and artistic basis. This last term is coming into common usage in both the elementary and secondary schools, and its use is spreading in higher institutions. Other suggested terms are "Eugenics" or "Euthenics" (freely interpreted, the art of right living). The term "household arts" covers all that has been included under the terms "domestic art" and "domestic science," together with other more recently developed industrial, economic, and hygienic aspects of home activities.

**Historical Development** — In certain forms, the subject has had a long history. In the theoretical treatises on education some phases of the subject are advocated in the sixteenth and seventeenth centuries, when Comenius (*q. v.*), and, in a more general way, Luther (*q. v.*), and many others emphasized the educational value of household activities. In the eighteenth century the philanthropists (*q. v.*) gave

## HOUSEHOLD ARTS IN EDUCATION

stronger expression to this belief, and at the opening of the nineteenth century Pestalozzi (*q. v.*) and other reformers began actual experimentation for educational purposes. Earlier than this the institutions of the philanthropists of Germany and the charity schools (*q. v.*) of England had emphasized such activities quite generally for practical purposes. The monitorial schools of Lancaster and Bell usually included some instruction of this character. Needlework was commonly found in all private schools for girls. Sewing especially had a high social status, and in the finer forms of lace making and embroidery was incorporated in the private schools for the well-born as a part of the "finishing education" of girls, so popular during the eighteenth century. The claims for recognition of the domestic arts of cookery, laundry work, housewifery, and needlecraft in the curriculum of school or college received sparse recognition in Europe before the middle of the nineteenth century. After that date their introduction into any scheme for the education of women or girls was for many years gradual, partial, and tentative. During the last twenty-five years, there has been developed a remarkable range of diversified and more or less highly organized courses of instruction in primary and secondary schools, technical institutes, training colleges, universities, and institutions working for social betterment. Peripatetic courses of instruction are arranged in many countries for rural districts; while post-school courses, residential or otherwise, provide for the needs of farmers' daughters or girls of the leisure classes. In the United States these subjects have received university recognition in the form of college courses for under and post graduate students. In Germany, the United Kingdom, and Ireland, and in Norway and Denmark, increasing attention is given to the study of the scientific principles which underlie the practical processes. In the United States about the earliest recognition of this field was given by Miss Catharine E. Beecher (*q. v.*), a pioneer in woman's education, who published (1840) *A Treatise on Domestic Economy for the Use of Young Ladies at Home and at School*. In England Hannah More (*q. v.*), in the late eighteenth century, had written on the subject. The local development of practical training relating to household arts subjects is given briefly in the sections on the separate countries. (See also BELGIUM, FRANCE; etc.)

**Aim of Instruction in Household Arts** — In its historical development the group of subjects may be looked upon as a part of the modern movement for an education that shall better fit for daily life, a so-called practical education. More specifically it is an effort to better the home life of the people, which originated everywhere outside of, rather than in, the school system. The movement in the schools was strengthened by the development of other handwork, the subjects formerly classed as

manual training, which included handwork for girls as well as for boys. The earlier realization that systematic school training in these home arts was desirable, and the later conviction that their importance justifies, if it does not compel, their adoption as school studies, are the outcome of. (1) the growth of preventive medicine and hygiene; (2) the desire to counteract the disintegrating influences upon home life and industry of modern industrial and social changes, (3) the recognition of women's needs in respect of technical and professional training, (4) attempts to solve the problems of domestic service.

If the fifteen or sixteen nations in whose educational institutions this teaching is now general are grouped into three divisions, the fact becomes apparent that the individual philanthropists or societies which started the movement in each country were prompted by one or more of these motives. State recognition and support is now invariably accorded with greater or less cordiality to this instruction, but the pioneer work has been uniformly carried out by philanthropic service and supported by private funds.

Three groups of countries may be made according to the underlying aims. (1) The amelioration of home conditions, and the improvement of existing domestic work and methods (United States, Great Britain, Ireland, Germany, Belgium, Finland, Denmark, Norway, and Russia). (2) The solution of the problem of domestic service, although there is now a tendency to move in the direction of the first group (Sweden, Holland, Austria). (3) Vocational and professional preparation (France, Italy, Hungary, and to some extent also Belgium and Switzerland). In Spain, Portugal, Greece, and Roumania the study of the domestic subjects is still in its infancy, and attention is limited only to one or two branches.

Much of the inspiration which led in 1889 to the simultaneous organization of cookery classes in Sweden, Norway, Finland, and Germany sprang from Great Britain, where the pioneer teachers in the first three of these countries secured their training. Though the standard of training varies very widely (from three years to six weeks), wholly untrained teachers are now permitted only in France and Austria, and in the rural districts of Switzerland, Norway, and Sweden. State inspection of classes is general throughout Europe. All teaching is gratuitous in primary schools, usually so in classes for factory workers, and occasionally for adults. Fees, when charged, are always low, necessitating heavy state and local subsidies. The urgent needs of the poorest classes dictated the utilitarian methods general in these courses; but in the girls' secondary schools of Norway, Belgium, Germany, Great Britain, and Ireland, the tendency is now to connect them closely with laboratory work in elementary science and with art studies in the studio. Contrary to the

usual custom, these subjects first found a footing in the secondary schools of Russia, Germany, and Denmark, but they are not yet generally adopted into primary education in these countries. Special training for matrons in institutions, asylums, etc., exists in Russia and Italy, Norway and Holland provide special instruction for soldiers and sailors. Efforts to solve domestic service problems by special training though attempted in several countries have had but moderate success.

**General Content** — When household arts began to form a subject of study in the United States, cookery, sewing, and housewifery were prominent. The need of scientific and artistic foundations was soon felt. Chemistry, physiology, and physics were early required in the course of Domestic Science. The science required was, however, elementary, but requirements have since been raised. Since the importance of the home for individual and social welfare has been recognized, emphasis has been placed on the principles and practices that have to do with the proper conduct of the home. The training of a better class of wage earners is considered on the industrial side, so that from this point of view household arts may be classed as a social science and as a branch of economics. Thus the subject has passed through three stages of development, all of which must now be given weight: (1) practical, (2) scientific and artistic, (3) economic and sociological.

The general divisions of these fundamental problems are as follows: (1) The food supply: its production, manufacture, transportation, and cost; good quality in food, food sanitation, pure food and inspection laws, how to buy, composition and nutritive value, dietaries and menus, preparation and serving. (2) Clothing and other uses of textiles: textile fabrics, their primitive beginnings, their connection with the development of civilization, textile arts and crafts related to clothing and shelter, modern manufacture and cost of textile materials, textile adulterations, functions of clothing and costume in health, beauty, and ethics of life, the wardrobe, its repair and care, the making of garments, hats, household articles and furnishing, design in textile garments and household furnishing. (3) Shelter: the cost of building, rentals, and taxes and insurance, house architecture, sanitation, and mechanics, household furnishing, for convenience, economy, and beauty. (4) Housewifery: processes of cleansing, preserving, and renovating all household materials, including laundering. (5) General management: the budget, accounts, savings, insurance; system in purchasing, inventories of household goods; household labor, relations of employer and employee; division and order of work; labor-saving apparatus. Town and state laws that affect the householder. (6) Care of the family: special needs of individual members, as infants, children, the elderly,

home care of the sick; family needs and duties; mutual occupations and recreations, hospitality; municipal and state responsibilities of the householder in connection with city and state sanitation (7) The employment of women in industries, their occupations, wages, clubs, settlements, pleasures, education, plans of betterment, woman as a citizen, and her relation to civics and the government

*Household Arts in the Elementary Schools* — Under the influence of the culture epoch theory (*q.v.*) many of the simple industrial and household processes have been introduced into kindergartens and the early grades of school. Courses in sewing under special teachers seldom begin before the fifth or sixth grade, and in many schools they are connected with lessons in design and discussions on textiles. The handwork in the better class of schools is on interesting articles connected with the home or the school. Previous practice of the stitches is given, but the "model system" requiring perfect work has long passed away. Organized courses in cookery and other forms of home work are not usually given before the seventh or eighth grade, although in view of the fact that many pupils are then likely to leave, they are advisable in the sixth grade. The subject usually includes lessons on nutritive values and buying. With the present tendency to give vocational training in the last few grades of the elementary schools, cookery, sewing, millinery, and dressmaking have been given an industrial bias, and are broadened and strengthened by academic and art work, as they apply to the occupations. To meet the exodus from the sixth and later grades many cities have organized special household arts' work in the afternoons. With this vocational preparation is also growing up very slowly a system of vocational guidance (*q.v.*).

The courses are still tentative, and need a further working out in practical correlation with academic work and art and with determination of the length of time which should be devoted to the different subjects and the elimination of unnecessary material. The domestic art work in the higher grades is usually conducted in the schoolrooms, although a special laboratory is provided in a few schools. Domestic science requires a special kitchen. Much discussion is centered about the use of individual equipment with small quantities of food and the group system around a large range or stove. Most school kitchens are now equipped for individual work on the part of each pupil. It is felt that this method helps to economize material and tends to develop the pupil's initiative, but it does not always give the ability to deal with the practical problems of cookery in the home as well as does the group method. Where the pupil cannot have enough material to make the process really practical, the best practice should include both individual and group work.

There are many practical questions of time

division and laboratory management and equipment, but at the present there is much divergence of opinion in different parts of the country. Definite results, therefore, cannot be given. In general it may be said that in the lower elementary grades the time allotted is usually from twenty minutes to one half hour. The processes and manipulation are simple, and are conducted by the regular teachers in the grade rooms. In the sixth, seventh, and eighth grades the common practice is three quarters of an hour twice a week for two years for sewing and one and one half hours once a week for one year for cooking. It is felt, however, for the latter subject that two periods per week would be better.

*Household Arts in the Secondary Schools* — Here the work in household arts is too new to have evolved an ideal course. There are different points of emphasis, in some cases there is an attempt to organize courses to secure college credit; in some the courses vary according as the previous training of the teacher concerned was in art or science, in other cases the previous training and the future of the pupils is taken into consideration. There is also considerable variation according to the type of school, thus the classical high schools, if they do not neglect the subject, offer it as an elective or require it for one year, perhaps with electives in later years, the manual training, technical, or practical arts high schools and the recently organized trade schools offer extensive work, often in close connection with business methods, when the students expect to become wage earners. The tendency is now not to leave the different subjects, *e.g.* sewing, dressmaking, millinery, cooking, etc., isolated from the rest of the curriculum, but the controlling aim is to give the students insight into the industries as they affect home and national life, into possibilities of greater economy in living, as well as higher ideas of woman's municipal responsibilities. Thus the courses are being gradually related to instruction in art, science, industrial history, geography, and arithmetic, and courses in home sanitation, chemistry of foods, nutrition, dietaries and menus on the one side, and household management, house furnishing and a study of costume on the other.

In the secondary school the method and organization are essentially the same as for the elementary, but longer time is given to discussion. The same principle holds good in regard to the number of lessons and the length of laboratory periods. In both domestic art and domestic science from thirty to forty-five minutes a week are necessary for the best development of the subject through discussion, which would include a review of the past laboratory work, plans for that which is to be undertaken, and the development of economic and social ideas. The teacher is much hampered by the lack of suitable textbooks, since those that are written accurately are usually too advanced for high

school pupils. The *Bulletins* of the United States Department of Agriculture, of the various associations of Textile Growers and Manufacturers, and the *Bulletins for Farmers' Wives*, published by Cornell University, afford material from which the teacher can assign some work to be discussed in class. Laboratory methods in the practical work in cookery and garment-making and in the housekeeping of the cookery laboratory do not differ essentially, although in some places the experimental method may be used to a greater extent and the pupils trained to work with a larger degree of independence.

In a technical or trade school, however, where preparation for a livelihood is given in the fourth year, a large amount of practical work, requiring at least four hours daily, should be included. The content of a course that counts for college entrance should be more intensive along scientific lines than one training for home work or for a livelihood.

*Household Arts for General Training in College and University* — Since the secondary schools frequently offer little or no preparation, the college courses in household arts are necessarily elementary. Domestic art offers a study of textiles including microscopical work on fiber, chemical testing, dyeing and weaving, art in the design of costume, interior decoration, household furnishing, household economics, and craft work in dressmaking and millinery. Many colleges now offer courses in foods and in the chemistry of nutrition and sanitation, which require not only elementary but organic chemistry and biology as prerequisites. Practical courses are given, but usually in the freshman year and sometimes not for college credit. Most of the colleges agree in placing a course in household administration in the senior year, presupposing a study of nutrition and some of the domestic art subjects. History of industry and at least one course in economics or sociology are also required in connection with the household arts' work. Where the subject counts for credit about one third of the students' time may be devoted to household arts.

*Normal Courses* — The content of these courses varies with the institution, but where diplomas, or degrees, or both are granted, there are given courses in art as applied to costume and house decoration, chemistry as applied to food and textile tests, biology, bacteriology, and sanitation, dietetics, practical work in cookery, millinery, and dressmaking, and housewifery, laundering being sometimes included. Courses in the study of textiles as applied to the economic training of the consumer are rapidly developing, and in addition, courses in pedagogy and practice teaching. The chemistry covers elementary (sometimes a prerequisite) and frequently organic chemistry of foods and nutrition, and in a few instances physiological chemistry.

In college, university, and normal schools the

method is parallel with the teaching of other college subjects. Lectures, discussions, and notebook work may be as accurately and scientifically conducted as in any of the natural sciences or academic studies. There is no dearth of sound reference books, so that readings may be assigned and required, although the majority of those dealing with textiles are written from the point of view of the mill and those on art in dress and home decoration are rather trivial. Here, and especially in advanced work, the opportunity opens up for individual research, with all the possibilities of exact training that such work affords.

#### Equipment and Cost of Maintenance —

These of necessity vary from country to country, from region to region, and from school to school. In some instances equipment runs to the extreme of expense and elaborateness, in others an effort is made to produce results with the simplest possible equipment, or at least that which approximates the home conditions, possible or actual, of the children. Equipment ranges from the simplest materials furnished by the child to whole buildings expensively furnished. Any statement of details would of necessity be of suggestive value only and can be obtained from much of the practical literature bearing on the subject, to which reference is given in the appended bibliography.

#### United States — Historic Development —

Instruction in the household subjects originated outside of the school system and in its modern form sprang from the renewed interests in all these lines at the time of the Philadelphia Exposition in 1876. The work was started in the eastern cities and was supported by private funds in classes outside the schools. Less successful attempts had been made earlier. In Boston an attempt was made to introduce sewing into the lower grades as early as 1854. This met with little success until 1865-1866. Special schools of cooking were established in the two cities. Public demonstrators and lecturers aroused public interest, and later a demand followed for the training of teachers. Cooking schools were begun privately in Boston, e.g. by Miss Joanna Sweeney in 1874, in 1877 by Miss Maria Parloa, later a teacher in the Fessenden Institute, whose president had been interested in the teaching of cookery in the South Kensington School. In 1879 the Woman's Educational Association of Boston voted to support a cooking school and made a contribution towards it, and on March 10, 1879, the Boston Cooking School was opened, in which demonstration lessons were given to young ladies, cooks, and girls. The school was put on a permanent basis in 1883, and in 1903 was incorporated with Simmons College. Cooking classes and kitchens were gradually provided in Boston schools and were taken over by the public school system in 1885. A normal class was held in the Tennyson Street School in 1886, and the Normal School of Cookery, which later

became the Mary Hemenway Department of Household Arts in the Massachusetts State Normal School at Framingham, was opened in 1888. The School of Housekeeping, which was incorporated with Simmons College in 1902, was opened as a private institution in 1897.

In New York City in the early seventies, the churches opened sewing schools. In 1876 the New York Cooking School was opened and was incorporated in 1878. It is now conducted in the United Charities Building. The Kitchen Garden Association of New York was incorporated on April 10, 1880, and included in its objects the promotion of the domestic industrial arts among the laboring classes. In 1884 this association became the Industrial Education Association. To meet the demand for teachers of sewing the first normal class was begun in 1884 as a part of its work. Instruction consisted of technical sewing alone, for methods of teaching the subject had not yet been completed. Classes in cookery and domestic art were held for public school children, and classes where girls could be trained for domestic service were also opened. In the winter of 1886 a children's industrial exhibition was held, representing sixty schools and institutions from different parts of the Union. This brought children's handwork before the public and had a direct influence in the development of the work in schools. In 1888 the College for the Training of Teachers, with a model school, was organized out of the Industrial Association, the name being changed to Teachers College in 1892. In 1911 the School of Practical Arts was differentiated from the other pedagogical departments and thus the household arts subjects again became a central object of instruction. As early as 1888 both cookery and sewing were introduced as regular subjects into the New York City public schools, one teacher being employed for each subject. Pratt Institute, Brooklyn, N. Y., founded by Mr. Charles Pratt, was opened in 1887, and science and domestic arts were included at the beginning.

In Philadelphia classes in cookery were offered by the New Century Club in 1878. These classes developed into a cooking school under the direction of Mrs. Rorer, which continued for twenty-five years. Drexel Institute, Philadelphia, was founded in 1891, and instruction was begun in 1892. Domestic science and art were important departments at the outset. Cookery and sewing were introduced into the elementary public schools of Philadelphia in 1885, and had found a place in the Girls High and Normal School in 1880.

The World's Fair at Chicago (1893) with exhibits from Sweden and other European schools gave an impulse to sewing as a school subject. In the fall of the same year the New York Association of Sewing Schools was formed and served as a center of information concerning courses, methods, and training, held conferences and exhibits, and issued publications; it grew

into a national society and had great influence in the introduction of sewing as an educational subject into schools of various rank in the United States. In 1901, the society, considering its work accomplished, was disbanded, for domestic art had become a part of instruction in educational institutions throughout the country.

In the West the movement began in the state institutions, Illinois, Iowa, and Kansas being the pioneers. Iowa seems to have been the earliest in domestic science, for at its opening in 1869 the young women students were required to work each day in the dining room and kitchen. Kansas Agricultural College reports the teaching of sewing as early as 1873-1874. In 1875-1876 lectures on food were given in the department of chemistry and a kitchen was fitted up in 1877. Women were admitted to the Illinois Industrial University (the State University) in 1870. The catalogue of 1871-1872 announced a School of Domestic Science and Art. In 1874 an instructor was appointed for this work. In 1875-1876 a well-organized course was printed in the catalogue.

*Present Status* — According to compilations made by the United States Bureau of Education in 1909 and 1910 sewing and cooking are taught in 95 elementary school systems, 207 high schools; and 142 higher institutions.

The most complete list is published by the *American Journal of Home Economics*, 1911, as follows: (a) Collegiate Institutions receiving aid from the Federal Government, 32; (b) Collegiate Institutions not receiving aid from the Federal Government, 102; (c) Normal Schools, 102; (d) Secondary Schools receiving State Aid for Agriculture and Domestic Science, 64; (e) High Schools giving courses in Home Economics, 632. Special Institutions (a) Schools of Domestic Science and Arts, 12; (b) Industrial Schools, 24; (c) Institutions for Defectives and Dependents, 26; (d) Part-time Schools, 26; (e) Institutions for Negroes receiving aid from the Federal Government, 17; (f) Institutions for negroes not receiving aid from the Federal Government, 69; (g) Institutions for Indians, 137. Total, 1243.

*State Universities*. — (The statistics quoted are taken from the *Organization List of Colleges and Experiment Stations*, 1900-1905, see Bevier and Usher, *The Home Economic Movement*. Those of later date were obtained through correspondence.) Arizona, 1900; Florida (State College for Women), 1906; Idaho, 1897 (dropped in 1899; two years' course added in 1903); Illinois, 1900; Indiana (Purdue), 1905; Kansas, 1910; Maine, 1909; Minnesota, 1900 (work for a degree, 1903); Missouri, 1901 (dropped in 1904; reorganized, 1906); Nebraska, 1898; Nevada, 1901; New York (Cornell), 1908; Ohio, 1896; Pennsylvania (State College), 1907; Tennessee, 1903; Utah, 1901; Vermont, 1908; Washington, 1909; West Virginia, 1899; Wisconsin, 1903; Wyoming, 1907.

*State Agricultural Colleges.* — A list of agricultural and mechanical colleges in the United States, published by the United States Department of Agriculture, Jan. 1, 1910, mentions sixty-seven institutions. Of these forty-seven are stated as having courses in Home Economics. Two more offer courses in Dressmaking. Of the forty-seven, thirteen are connected with state universities and appear in the list of those institutions in the preceding paragraph. This leaves thirty-four state institutions which offer such courses.

*Private Colleges.* — Well-organized courses are now offered in many of the endowed colleges and technical schools of the middle west. The work in the South has developed well in the normal and industrial colleges. In the East, Brown University has included work in home economics since 1903 in the Woman's College. Simmons College, Boston, incorporated in 1899, opened in 1902, to aid young women to self-support, numbers the School of Household Economics among its four schools. The Women's colleges of the East, Bryn Mawr, Mt. Holyoke, Smith, Vassar, and Wellesley, do not offer it, although they give courses in applied science, economics, and sociology that would be included in the home economics subjects in those colleges where such departments exist. Vassar, for instance, offers a course in household sanitation and in the chemistry of foods, Bryn Mawr a course in methods of social research, and a graduate course in problems of nutrition (1909-1910).

In the colleges and universities most of the courses offered count for the degree of B.S. Graduate work leading to the M.A. is also offered. In the University of Chicago the home economics course counts for either A.B., B.S., or Ph.D. The subject counts for college entrance to a very limited extent. Chicago and Illinois give two points credit each. At the University of California domestic science under certain conditions counts from one and one half to six units.

In 1907 the North Central Association of Colleges and Secondary Schools accepted household arts and sciences under the manual training group, the subjects to count as follows: plain sewing, one unit, sewing and millinery, one unit, cooking, two units. The revised Regent's Syllabus for the state of New York, 1910, includes syllabi of sewing and textiles and foods, which may prove a step toward the counting of the subject for college entrance. A number of committees are at work on this subject, but progress is of necessity slow.

*Secondary Schools.* — The growth of the work in the high schools was at first somewhat slow, but with the opening of the manual training high schools in different parts of the country, the number of schools giving household arts increased notably. Among these were the manual training high schools, Saginaw, Mich., Los Angeles, Cal., Providence, R.I. The

establishment of the technical and vocational high schools has more recently added many to the list of high schools, as, for instance, the technical high schools of Cleveland and Cincinnati, Ohio, Newtonville and Springfield, Mass., the Cosmopolitan High Schools of Toledo, the Washington Irving School of New York City, and the William Penn of Philadelphia. Others to be noted are the Practical Arts High Schools of Boston, and New Bedford, Mass. Other cities are following the lead of these schools and in a few years every city will have its high school of practical training in which household art has an important part. Night schools in all of the large cities also offer technical courses of high school grade, which aim to affect the art of everyday living and the organization and management of the home. For fuller discussion of this movement, see INDUSTRIAL EDUCATION.

*Special Institutions.* — Notable among the schools that may be classed as philanthropic are the schools or classes connected with the Young Women's Christian Association throughout the country. In larger cities there are well-developed departments which are also beginning training for domestic service.

Courses in the household arts are now given in a number of summer schools. One of the pioneers in this field was the Chautauqua Summer School, where demonstration lessons in cookery were given as early as 1879. In 1900 well-organized courses were offered, the work now covering a period of six weeks. The American School of Home Economics is a correspondence school of good standing having its headquarters in Chicago. This school has been valuable not only to housekeepers, but its publications of twelve volumes have been helpful in school work. The Lake Placid Conference of Home Economics, founded by Mr. and Mrs. Melville Dewey in 1899, has developed into the American Association of Home Economics, organized in Dec., 1909, with a magazine, the *American Journal of Home Economics*. Various branches of this Association exist in different parts of the country. The subject, too, is discussed in other associations of teachers and is becoming a prominent feature in the farmers' institutes and granges. New York City organized the Manhattan Trade School for Girls in 1902 and Boston followed in 1904 in the Boston Trade School. Both were at first under private control but were later taken over by the Board of Education. These schools attempt to reproduce trade conditions in their instruction; consequently they are organized as small factories. To aid the trades and to develop a higher class of work, art, and academic courses adapted to the specific needs of each of the trades represented in the schools are given. Wholesale and custom work are taken in all departments. A system of business shops headed by trade workers who can teach as well as conduct workrooms

gives the students real business organization under which to work. The results in both schools show that such practical instruction enables the workers to enter better positions, to gain higher wages, and to continue to rise to more influential situations.

*Training of Teachers* — The training of teachers of domestic arts for elementary and secondary schools now finds a place in many normal and in many university schools of education. The training for trade school teachers is not at present as well organized as in Europe but has been begun at Simmons College, Boston, and at Teachers College, Columbia University.

The formal training of teachers was begun in the Boston Cooking School, the Boston Normal School of Cookery, the New York College for the Training of Teachers, Pratt Institute, and Drexel Institute. From these centers, and from the Kansas Agricultural College, teachers were supplied for the new work all over the country. A one-year full time normal course was offered by the Teachers College in 1890, the course leading to a diploma. Up to this time a three-months' course with a certificate was all that had been offered by this institution. At the present time the University of Chicago and Columbia University train teachers of the household arts, the former in the School of Education, the latter in Teachers College. Several of the state universities and agricultural colleges afford such opportunity. Pratt and Drexel Institutes continue their normal departments. Of 147 public normal schools in 1910, 103 schools offered one or more branches of household arts. Of the 42 institutions listed in the *Lake Placid Report* as training teachers (1907) only seven were state normal schools or colleges. The demand for household arts in the state normals is on the increase, however. This is due probably to the awakening in regard to rural schools and the quickening interest in household arts teaching.

*Training for Professional Service* — The training in America for higher professional teaching is helping to develop still other vocational positions for women. Leaders of culture, artistic knowledge, executive ability, social and industrial intelligence and business knowledge, are needed for such positions as institutional directors, managers of settlements, welfare workers, social secretaries, costume designers, interior decorators and craft workers. There is also an evident inclination to consider that highly educated and trained women can be successful as heads of large business houses for dressmaking, millinery, and embroidery, or for foreign buyers. These demands may lead to the offering of degrees for women corresponding to those in the engineering courses for men.

Domestic art has become an important factor in the medical profession and is used increasingly in work for epileptics, insane, and feeble-minded. Orthopedic hospitals, insane asy-

lums, blind asylums, orphanages, workhouses, and reformatories find in it a valuable subject which while offering practical help also has an ethical and hygienic bearing. Settlements, churches, and social clubs are also using the various subjects to help them in their work of betterment and in fostering a wise enjoyment of life.

M. S. W. AND H. K.

*Great Britain and Ireland* — References to the importance of attention to domestic economy in the education of well-to-do girls are found in the writings of Hannah More, Erasmus Darwin, and other educationalists in the eighteenth century. In 1840 needlework was "expected" in national schools for girls and infants; it became compulsory in 1862. In 1846 also the Privy Council Committee on Education considered the propriety of granting a gratuity to schoolmistresses who taught domestic economy successfully in these schools, the reports of various Royal Commissions having drawn attention to the appalling home conditions of the laboring classes. School kitchens and washhouses were equipped in certain "industrial" schools, and during the next fifteen years frequent reference is made to the instruction of the female apprentices (pupil teachers) in "domestic industry." The Privy Council concluded, however, in 1860, that as school laundries and kitchens were "expensive to establish, expensive to maintain and difficult to conduct," they would no longer "press for them," but directed that attention be concentrated upon needlework. Henceforward until 1875, domestic economy was taught sparsely and by theory only. In that year practical instruction in cookery under trained teachers was "recognized" by the Board of Education, and in 1878 the plan of cookery "centers" was started for primary schools, government grants for such classes in day and evening schools were first made in 1882-1883. A few years later experimental classes in school laundry work were held in London under a joint and most representative committee; but the subject was not admitted into the code until 1889-1890. Eight years later "practical housewifery" was officially "recognized" by the Board of Education. Another ten years, and domestic science was introduced viz the experimental study of definite problems in hygiene and domestic economy. All these terms were superseded in 1905 by that of "domestic subjects" (cookery, laundry work, household management, dairy work, needlework, elementary dressmaking). At this date the curriculum was recast and household subjects were definitely regarded as a part of the program in all public elementary schools, including special schools for mentally and physically defective children. A circular was issued in 1911, and the new term, "housecraft," was introduced. Domestic classes for adults, directly designed to improve the conditions of home life, were established all over the country in 1890, as a result of the

money made available through the Technical Instruction Act of 1889. These stimulated the provision by numerous private schools of courses, residential and otherwise.

Women inspectors of domestic subjects were appointed by the government in 1889. The official recognition of domestic subjects in secondary schools is relatively recent (1906); admirable courses are now becoming general, in which laboratory and art work are correlated with the practical domestic arts. Post-school courses increase in popularity, while the example set (1908) by King's College for Women (University of London), in its post and under-graduate courses in household economics, is soon to be followed by other universities. Scholarships for the residential housewifery centers and trade school courses for girls on leaving the primary schools indicate other lines of progress in large cities. Boys are taught cookery in the seaports of three counties. The provision of instruction for girls over eleven in primary schools remains quite inadequate, though in 1909-1910 instruction in cookery was given to 316,233 pupils, in laundry work to 118,040, and in combined domestic subjects to 6707. Needlework remains obligatory for all girls, but is now discouraged in infants' schools.

The revival of interest in 1875 was due to the lectures on the art of cooking given by Mr. Buckmaster at the International Exhibition, London, 1873, 1874 saw the foundation of the National Training School of Cookery, the first of these "recognized" by the Board of Education for the training of teachers, as well as for the instruction of the public. Though some of these schools are now under the management of public education authorities, they were all founded by private effort. Their union for examination purposes dates from 1876, it developed in 1889 into the influential National Union for the Technical Education of Women in the Domestic Sciences, to whose persistent efforts much progress is due. So great was the demand for teachers that many more training schools were opened in the nineties (thirty were "recognized" in 1897), when new subjects were added. Each training school issues its own diploma in cookery, laundry, housewifery, needlework, and dressmaking, under specially defined conditions, the requirements in general education and special training are being steadily raised, in spite of financial difficulties which have crippled their efforts. None but trained teachers have ever been sanctioned, their Association, with a membership of 1100, was founded in 1896.

**Wales** — In the Welsh primary schools domestic art classes are on much the same lines as those in England. Twenty-nine out of thirty-three local authorities made provision for 90,000 girls from these schools (1907-1908). The first training school for the domestic arts was established at Cardiff, 1892. Cookery and laundry work are now taught in most of the

girls' secondary schools in Wales, and a new three years' home-making course (four hours a week) appears in the program of the "mixed" higher elementary schools at Glamorganshire. This county has by its enterprise in the initiation of new developments in these subjects exercised great influence for good on adjoining local educational authorities. These include a wider (*e.g.* carpentering, care of children) and reorganized curriculum, a greater emphasis on the scientific and educational aspects of the domestic arts, with no loss of the practical spirit; a more consistent and closer connection with general education and home life. Special rooms to facilitate these methods are a feature in new schools. A short course is now offered to students at the University College of North Wales.

**Scotland** — Needlework is obligatory in girls' primary schools in Scotland, otherwise cookery, of which the organization now corresponds generally with that in England, is the only domestic subject taught. At first (1884) demonstration classes were frequently given to a hundred pupils, though practice was always limited to twenty-four. Peculiar to Scotland are the "supplementary classes," entered, after a qualifying examination, by girls over twelve, from the primary schools. Nine hours a week for from two to three years are devoted to domestic science, while the general education is also proceeding. There are twenty-six such supplementary centers in Glasgow alone, with an attendance of over 2000 girls. The first Training School for Cookery was founded in the early eighties in Edinburgh, as a result of Mr. Buckmaster's lectures, though official efforts to give a more practical character to the examination in domestic economy of female candidates for the teaching profession date from 1859. No recognition is yet accorded to the domestic arts in the secondary schools for girls in Scotland.

**Ireland** — No decided interest in domestic subjects was taken in Ireland before 1886. The City of Dublin Technical School organized classes in cookery, dressmaking, and laundry (the latter unsuccessfully) in 1887. The Dublin School of Cookery, Laundrywork, and Dressmaking, which owes its initiation to the Royal Irish Association for Promoting the Training and Employment of Women, in connection with the Association for the Technical Training of Women and the enthusiasm of private individuals, dates from 1893. It was taken over in 1903 by the Department of Agriculture and Technical Instruction, with the object of training teachers, though short courses are given to women of all classes. It is now described as the Irish Training School of Domestic Economy, and considerable attention is given to the sciences fundamental to the arts of cooking and cleaning. A residence house was opened in 1909, where students undergo a period of preliminary practical instruction, before the two-years' course for teachers. A special one-

year course in housecraft was organized in 1910 at Alexandra College, Dublin. Three residential schools for well-educated girls were established at the Ursuline convents at Waterford, 1904, and Shgo, 1908, and in Londonderry, 1908, under the management of Victoria College. Eight corresponding residential schools for working class girls are scattered over the country. Domestic subjects are also taught (1909) in sixteen municipal and thirty-seven technical schools in Ireland. Courses in every branch of domestic economy, which admirably combine the practical with the educational, have been carried on since 1901 in fifty-eight girls' secondary schools, under the Department of Agriculture and Technical Instruction. They are described respectively as "auxiliary" (two years) or "special" (four years), and are obligatory on all pupils. Needlework has always entered into the primary school program. Cookery, laundry, and hygiene classes were introduced in 1896.

**Denmark** — A few advanced educationalists advocated the introduction of domestic economy into primary schools between 1870 and 1880, but needlework and hygiene only were taught. The first school for the training of servants was started in 1872 by the Crown Princess Louise, and has remained the most important among its successors. In the nineties several housewifery schools were started by private individuals at Copenhagen and in a few provincial towns, of these some are residential courses, two to nine months. All have very moderate fees. A tentative plan for introducing cookery and laundry work into the primary schools of Copenhagen was adopted in 1893, but it was 1898 before voluntary classes were opened for the elder girls. Continuation classes were organized for workers from fourteen to twenty years of age at the same date.

The domestic arts are now compulsory (four hours a week) in the primary schools of Copenhagen and Frederiksberg, for girls in Class VII, age twelve to fourteen years, and in a very few provincial towns, nowhere in the country. Copenhagen and Frederiksberg have twenty-three centers — provincial towns twelve. These subjects are taught in eight secondary schools in Copenhagen and at seven in the provinces. Peripatetic teachers are employed in rural districts by various associations of women. Sixty to one hundred and sixty hours of instruction are given to women and girls for a nominal fee. Little provision is made for the technical training of girls in Denmark, though the State subsidizes a school for professional dressmakers in Copenhagen and another for seamstresses. University courses on the allied subjects of hygiene, chemistry, biology, etc., are accessible to women, and a state grant for further experimental work in domestic science was voted in 1905 to Fru Berg Nielson, one of the earliest advocates of housewifery teaching in schools. Practical demonstration courses

in dietetic cooking have been also organized at the university for young medical men.

**Sweden** — A school of household training for girls was opened by a committee of ladies at Gothenburg in 1865. The first of a series of schools for servants was started in 1870 at Stockholm by Froken Hedda Cronius, to which shops were attached for the sale of cooked provisions; but the first cooking classes in Sweden date from 1882 and are due to Fru Hierta Retzius, whose name will be always honored in connection with the great work she pioneered in that country. The school was self-supporting in two years. It was presented by its founder in 1893 to the Higher Training College for Women Teachers, with the sanction of the government, to secure trained teachers in secondary schools for girls, with the result that in 1908 twenty-eight out of thirty-seven such schools were eligible for the government grant in this subject. The instruction is carefully correlated with lessons in natural science, hygiene, bookkeeping, etc. Courses last one to three years, with one lesson a week. The State subsidizes four other training colleges for teachers in primary schools in towns and one for those in rural districts, the courses last about eight to twelve months, fees vary, but are all low. A union of Swedish teachers was formed in 1906. A bill was passed in that year making an annual government grant of 60,000 kr., to promote this instruction in primary schools, higher primary schools, and people's high schools. No fees are permitted, classes are limited to twenty, the bare cost of the food is charged for the dinners, etc. School courses usually cover two terms — four hours a day — one day a week. Boys learn cooking in some of the seaport towns and in one agricultural school, they also help the girls in the kitchens of the twenty "children's workshops," organized in Stockholm. Forty peripatetic courses are at work in twenty-one of the Swedish provinces, giving from five to seven courses of six weeks' duration each year to from fifteen to twenty pupils at each course. A large number of private *écoles de fiancées*, with very complete courses, also exist in Sweden. Courses are provided for work girls in some factories. The rapid development of this teaching in Sweden is sometimes attributed to the admission of women to the administration councils of schools.

**Norway** — Great efforts to improve the education and general conditions of the people were made after 1814. Public opinion was educated by means of books and of a journal, concerned with the need for greater efficiency in daily life, which appeared 1860-1870, under the auspices of the Society for Promoting Popular Education. Fru Mina Weltesen founded the first school for domestic training at Abildso, near Christiania, in 1865, and carried it on successfully for sixteen years. The movement grew rapidly after the establishment of the first school kitchens at Christiania.

in 1889. Now cookery courses are given in the primary schools of every town. The system is a combination of the English and German. Instruction is closely correlated with science work. Housekeeping appeared in the program of girls' secondary schools in 1896, and is now a subject for examination at the age of fifteen to sixteen. Needlework is compulsory in all schools. Trained teachers were employed from the first in all state schools, special short courses being arranged for ordinary staff teachers. Two years' courses in housekeeping were introduced into training colleges in 1902, and the government grants include traveling scholarships for selected students. Chemistry and physiology must be studied at a university, and the domestic arts at a training school of domestic economy. General pedagogical training is also insisted upon, in order to utilize the educative value of these practical subjects, to permit of correlation, and to dignify it in the popular estimation. Excellent private housekeeping schools have been organized in different towns by private individuals or by societies, such as the Society for Furthering the Interests of Women. Some of these are self-supporting, others receive grants from the government, municipalities, benevolent societies, etc. They are largely frequented by young ladies. Courses adapted to the needs of working women are also provided. Free instruction is provided for one third of the pupils in the provincial residential housekeeping schools, with a nine to ten months' course. The province defrays one quarter total expense, government defrays three quarters. The subjects of instruction are cookery, garden, laundry, dairv, needlework, chemistry, physics, biology, hygiene, etc. Short peripatetic courses of cookery and household management given by trained teachers are organized in some country districts by the Agricultural Society. Residential schools for the training of girls as domestic servants exist in Bergen and Christiania, with a two years' course. Cookery courses have also been carried on for soldiers since 1900, while the first school for the training of ships' cooks and stewards dates from 1893.

**Finland** — The movement was distinctly educational from the first, and well supported by trained teachers, many of whom took the course in *Ménagère Pédagogique* provided by the people's high schools, others being trained for shorter or longer periods at the training schools now available for the purpose. The interest of the Association of Finnish Women was first aroused in the subject in 1889, when the organization of training upon educational lines was determined upon. Subscriptions sufficed to send Mlle Anna Olsoni (Mdm. Quist) to study the subject in Sweden and Great Britain. After taking her diploma at Glasgow in 1890, she returned, and in 1891 became superintendent of the Helsingfors

School of Training in Housewifery, at first supported by private subscriptions, the pioneer of many successors at, e.g., Kripio, Tannefors, and Niborg. Courses were and are offered to teachers (for whom employment in schools of different grades is subsequently insured), for girls on leaving school, for young peasants, and in high class cookery for ladies. In 1907 this society organized no less than twenty-three peripatetic courses, with 293 pupils, from fifteen to forty years of age. The fees, five to fifteen francs, are supplemented by grants from the State. In 1892 a great impetus was given to the movement by the formation of a new union between men and women to work, in concert with the Martha Society, for the advancement of women's education, with the assistance of grants from the State (3000 francs per annum). Courses, varying in length from four days to six weeks, have been organized by forty of its branches all over the country, and a residential school for twelve pupils has been opened at Kolaris in Lapland. Cooking is not generally taught in elementary schools, though the instruction of girls has always included needlework and knitting, to which the use of the sewing machine is now added. Ample provision for its acquirement is provided in higher grade schools or by means of classes for adults.

**Russia** — The first cookery school in Russia was opened in 1880 by the Society for the Protection of Public Health in St. Petersburg. In 1888 a technical school for girls and women was founded, which has now over 200 pupils. In 1890 a second cookery school was founded in Moscow by the Society for Propagating Practical Knowledge among Educated Women, from which eight professional schools have sprung. It supplies matrons for asylums, hospitals, etc. Four years later the Society for Encouraging the Professional Training of Women opened a similar school in St. Petersburg. Over 1200 students gained appointments in the first six years. Large numbers of scholarships are given by private individuals and societies of importance.

The teaching in the Russian training schools is of three types, and generally is associated with training in agriculture. (1) courses in St. Petersburg for the higher study of these arts, designed for girls who have completed their secondary school course, to prepare them for independent work in agriculture and farming (1907, 255 students). (2) So-called "Stebut courses," from the name of their originator, of which there are three near Moscow and Skov, designed for girls from higher elementary schools, these give both theoretical and practical instruction in both branches of knowledge (1907, 120 pupils). (3) Schools of a more technical character, of which there are twenty-one dispersed over the country under the Department of Agriculture, which give very full and thorough courses of two to three or four years, mostly free for the farmer class. All these

schools are subsidized by the government to a total sum of 36,000 roubles. There are also a few similar schools under the Ministry of Public Instruction. Schools of cookery exist at Kiev, Odessa, Tiflis, and other large towns. So far the subject is not taught in the public schools, but it is required in institutions for orphan girls of noble birth.

**Holland** — Great attention is given in Holland to the training courses for teachers and others. These are comprehensive, and include physics, chemistry, physiology, hygiene, book-keeping and laundry work, as well as cookery and dietetics. Diplomas are granted after examination by the Union of Teachers of Household Arts (founded in 1900), which is subsidized by the Dutch government. This union organizes vacation courses for its members by specialists; possesses an excellent library, publishes an annual report upon the teaching of housewifery in Holland, and is associated with a Bureau of Women's Employments. The Departments for Army and Navy require that a proportion of soldiers and sailors shall attend cooking courses, specially adapted to their requirements, while other courses are arranged for recruits to the colonial army. Members of the Association of Nurses and Sisters of Charity have their special courses also. The new Housewifery School at Amsterdam has further organized successful courses in dietetics for doctors and medical students, the lectures on biological chemistry and invalid diet being given by university professors and supplemented by practical work under the supervision of the school staff. There is a municipal school for training domestic servants at Amsterdam, as well as corresponding courses at the Hague and elsewhere, these last being due to private initiative. Twenty-one housewifery schools have been founded since 1888, which are kept in close touch by their monthly journal. Nine prepare girls for examination in handicrafts, domestic and otherwise, accounts, bookkeeping, cutting-out, dressmaking, and the care of children. The remainder grant diplomas of various grades, professional or otherwise, in housewifery and cooking only. The majority of these schools receive grants from the State, the province, and the city, where they are situated. The numerous classes for working girls and women owe their origin and spread to various societies concerned with the public welfare, as well as private individuals, and to these sources is due the provision for the training of philanthropic workers. School instruction in practical cookery and laundry work is, so far, confined to a few primary schools in Leyden, the Hague, and Amsterdam; but twelve of the chief cities offer useful courses on leaving schools to girls who have gained their certificates, and the training schools provide evening classes and others for the general public.

**Belgium** — The first administrative measures to promote the teaching of needlework in schools

were taken in 1874, though the subject only became compulsory in 1879. Technical training for women, designed to relieve the poverty and unemployment brought about by industrial changes, originated in 1844, and cookery classes for their work-people were organized from 1871 onward by one large firm after another, but the ample provision for training in the domestic arts by which Belgium is distinguished, is the direct outcome of a grave social crisis — the strike of 1886 — to which the inefficiency of housewives was believed to be a contributory cause. Organized instruction, broadly speaking, dates from the year 1887. Public institutions for the necessary instruction of adults were soon opened by wealthy governors of provinces or societies, and after the experimental stages were passed received grants from the State, which subsequently imposed its own regulations (1889). Great elasticity is permitted to meet local needs, and every effort is made to fix hours convenient to young workwomen. A complete course usually extends over two years. These classes are considered the continuation and rational completion of the primary school course. Great impetus was given to this movement in primary schools by the central and provincial committees of influential women instituted for the purpose by the Royal Decree in 1880, it spread in 1881 to fifty secondary schools for girls, where three years' courses, essentially experimental and practical, now lead up to a diploma of capacity (instituted 1893), granted upon a syllabus and examination defined by the State. At the same time provision was made for the training of the necessary teachers at Brussels and elsewhere, at first by short temporary and holiday courses, until time permitted their more complete preparation. Hygiene, domestic economy, and needlework are taught in three out of the four years spent at a training college, by inductive, experimental, and practical methods. All instruction is under the direction of the Ministère de l'Intérieur et de l'Instruction, or of the Ministère de l'Agriculture, de l'Industrie et des Travaux Publics, according to whether it deals with adults or pupils still at school. The courses in housewifery are usually brief, limited, and theoretical, for the State does not advocate teaching the practice of these arts at this stage. Inspectors find that adults profit from the teaching far more than do children, though the system of instruction at centers is being introduced at Brussels, Bruges, etc., and is developing in connection with the *cantines scolaires*. Admirably organized work is carried on by the *écoles professionnelles et ménagères*, which provide courses of from two to three years, and the *écoles ménagères*, which have courses of from one to two years, for girls from fourteen and upwards of varied capacity and social standing — chiefly lower middle class. About 300 of these schools existed in 1901, and their number is reported to have largely increased, while their pupils

number many thousands. In each *école professionnelle* (trade school), domestic economy and gymnastics must be taken in the general course; but in the other two types of schools mentioned, one half or the whole time respectively is devoted to every branch of the domestic arts. Grants are given for outfit, and an annual subsidy of two fifths the expenditure is made to those schools which fulfill state requirements. These trade, agriculture, or domestic schools may be under private or municipal control. Many bursaries are given, and fees vary widely, according to the means of the pupils. No peripatetic teachers or ambulatory schools are permitted in Belgium.

**Germany** -- In 1792 Hippele, the friend and disciple of Kant, when advocating the higher education of women, drew attention to the need for special training in domestic methods, on account of their influence on human well-being, but the first efforts made, a century ago, to arouse interest in the subject, resulted chiefly in the establishment of schools for training servants, of which many were founded between 1815 and 1875. In Germany, the movement is the outcome of private initiative, and is warmly supported by Women's Societies, large employers of women's labor, etc. These societies, of which the *Lette Verein* at Berlin was the first, sprang into life between 1850 and 1860, though it was 1873 before the Grand Duchess Louise of Baden, with the support of the Women's Association, founded the first housewifery school at Karlsruhe, cookery classes for adults were started in Berlin in 1885, at the instigation of the Crown Princess of Prussia, who, also, in 1888, secured some housewifery instruction for working girls. Fraulein Foester pioneered the first cookery classes in a girls' primary school in 1889. Munich, Nuremberg, and Augsburg followed the example of Cassel, and added an optional eighth class, devoted chiefly to a very complete course in housewifery, which is closely correlated with general education -- no special teacher being employed. Thus organized instruction in domestic subjects came into being relatively late, though great strides have been made in the last twenty years, witness the *Official Code for Higher Girls' Schools in Prussia*, 1908, which requires that at least one year's training be given to each girl in housecraft, the rearing of children, and kindred subjects.

So great a variety of agencies are now engaged in the promotion of this instruction, that, in the absence of imperial reports and statistics, it is difficult accurately to describe their work. Sewing schools of a high standard were the first technical schools for women to get a firm footing in Germany, needlework is taught in every grade of school, classes being provided also for adults. The state and municipalities have only quite recently founded technical or industrial schools for girls, such as are found in Berlin, Leipzig, Dresden, Munich, Stuttgart, etc.

They owe their existence to private enterprise, and have, unfortunately, no common standard. The *Fortbildungsschulen*, which now cover the country, and the *Fachschulen* (see INDUSTRIAL EDUCATION) include domestic art courses for teachers as well as pupils. Many teachers are trained locally, or in Berlin at the Lette Haus and the Pestalozzi-Froebel Haus (*q v*). Since no national regulations exist for this purpose, great diversity of requirements are found. State grants are made chiefly by the Departments of Commerce and Agriculture. The former founded model state housewifery schools at Rheudt, Potsdam, and Posen, 1902. Great opposition exists to making these subjects compulsory in primary schools, but many private societies endeavor to supplement the omission. When given, school authorities are responsible for all the arrangements made. The chief distinctive characteristic of Germany is the large development of residential home-making schools (those of the *Diakoniewerein* give all lessons in relation to the practical needs of life). They are frequented by middle-class girls, who pay good fees for one and a half year courses. Reference must be also made to the Society for Country Housewifery Schools (1897), founded by Frau von Kortzfleisch and assisted by the Minister of Agriculture; also of the traveling cooking schools for rural districts, now at work in Baden, Bavaria, the Palatinate, Lower Franconia, and the Rhine provinces.

**Switzerland** -- The most striking features are the rapid spread of such instruction, which is taught entirely as an applied art, not as science, during the past ten years, and the accessibility of the classes. Courses are given in the primary schools of a few towns and communes, but are universal in *Fortbildungsschulen* (continuation schools), *Arbeitschulen* (trade schools), *Haushaltungsschulen* or *écoles ménagères* (housewifery schools) -- resident and non-resident. Short courses are provided for factory and other workers, in urban and rural districts. A close alliance between private societies and governing authorities does much to forward the movement, which sprang, in 1881, from the desire of a group of private individuals to improve the teaching of needlework. This became obligatory in schools in 1878, and is now carried to great perfection in the trade schools at Zurich, Geneva, etc., which confine their training to needlecraft, housewifery, and commercial work. 1881 saw the foundation of the first of many succeeding *écoles ménagères*, by *La Société d'Utilité publique des Femmes*. There are many of these residential housekeeping schools offering courses from three months to one year; their fees vary, but are very low.

In 1895 the federal government decided to make grants to these and similar institutions, for training women in trades for the domestic arts, which from the first had received liberal subsidies from the cantonal and local authorities.

Trained teachers were drawn at first from Germany; now training schools exist at Berne, Zurich, Fribourg, Geneva, etc. No general syllabus is yet imposed. There is inspection by the federal inspectress, but a good deal of freedom is sanctioned. In Geneva girls must proceed, at the close of their sixth year in the primary school, either to a secondary school, where there are now optional courses in the domestic arts, or to an *école professionnelle et ménagère*, for at least two years, where one half of the time is given to these subjects. Other towns are imposing similar regulations. The training of servants continues at Berne, Fribourg, and Winterthur, but has not so far effected a solution of the domestic problem. Elaborate courses, domestic or professional, in every branch of needlework, are offered at a large number of special schools throughout the country; they vary in length from a few weeks to four years. Very few of these classes are free, as is constantly the case with those concerned with cookery only.

**Austria and Hungary** — In the eighteenth century the Empress Maria Theresa (*qv*) issued a general ordinance, requiring that girls be taught the best methods of sewing, knitting, and domestic economy in every school, but a century elapsed before the two former were introduced into elementary education. The whole group of subjects was made obligatory in 1869, but the regulation as to housewifery remained a dead letter and was suppressed in 1883. Opportunities for instruction in cookery are still chiefly the result of private enterprise, though latterly some education authorities have recognized the movement. In Hungary, especially, this has occurred, and instruction is given to the girls in the *Repetition*, or higher grade schools. In Buda-Pest there are thirty-six such schools, numbering 4000 pupils. Cookery is also taught in the technical schools of that city, and in the normal colleges for women teachers, but nowhere yet in elementary schools, though, through the persevering efforts of private and educational societies, courses are in some instances provided in an annex to the schools, supported by fees and subscriptions. Austria and Hungary are chiefly responsible for (1) the schools for servants and others attached to restaurants for the sale of the food cooked, started in 1883 by the Society of Housewives, taught by expert but untrained teachers. In 1906 the Union of Hotel Keepers combined with the country housewifery schools to provide a one-year course of training for teachers, from which much stimulus is expected. (2) The local farm or housewifery schools, founded by agricultural societies in the various provinces, for the daughters of better-off peasants after leaving school. These include in their very practical curriculum the care of children and sick nursing. (3) The general provision by factory owners and philanthropists of free cooking

classes for working girls (three months' courses, five evenings a week), which now number over 2000 — twelve pupils to a course. Untrained teachers are the great obstacle to progress, as well as the absence of state interest and aid. Both are probably due in part to the peculiar racial conditions and difficulties of the Empire. Official attention has been concentrated for years upon technical as well as school and normal college training in every branch of the finest needlework for women and girls. In the large and efficient trade schools and technical institutes scattered all over the Empire, general and special instruction is given in lace work, lingerie, dressmaking, millinery, embroidery, design, drawing, and painting.

**France** — Needlework was recommended as a school subject in 1850, and made obligatory in 1882, when practical teaching of the domestic arts was officially, though not actually, introduced into primary and secondary schools, an *école de ménage* was instituted at Rheims in 1873, with a three years' course for girls on leaving school, similar *cours complémentaires* were organized more generally in 1884-1887. But the practical teaching of cookery and housewifery has been generally brief, restricted, and theoretical, attention being concentrated upon elaborate needlework. The movement to perfect girls in this art was begun in Paris in 1842, a society to cope with its rapid development was formed in 1856. Since 1886 these *écoles professionnelles* have steadily grown in scope and importance. The mornings are devoted to general education, the afternoons to technical training in every branch of needlecraft, dressmaking and cutting, millinery, etc. There are eight such municipal technical schools (*écoles pratiques de commerce et d'industrie*) in Paris, with an average of 300 pupils each. Instruction is free, scholarships being granted for clothes and meals. In the *écoles professionnelles ménagères* (technical schools), each pupil must have eight weeks' practical cooking, laundry work, and housewifery during her three years' course; but in part as the result of the relatively high level of cookery in France and the belief that such training should be given in the home, practical teaching in these arts is still far from widespread. The *Orders* of 1887-1888-1889 remained dead letters, but a great extension of the movement dates from 1897, when the establishment of a training school was required in every town of over 50,000 inhabitants, and *classes ménagères* became obligatory for girls over thirteen in every urban school numbering over 250 pupils. Considerable incentive was given by the conclusions on the subject formulated at the International Congress on Primary Education held in Paris, 1900. *Cours complémentaires manuels et ménagers* for girls holding certificates from the primary schools were established in 1901, which cover two years, with a weekly total of thirty-seven and a half hours; and a three years' course pro-

vided for girls up to sixteen or seventeen in the *écoles primaires supérieures*, in which needlework, dressmaking, millinery, and hygiene are included. Though students in the training colleges for primary teachers do their own housework, training is only given in needlework and dressmaking, two to three hours weekly for three years. In one or two cases in the *lycées de jeunes filles* (public secondary schools for girls) optional demonstration courses are offered, given by the cook of the establishment, they are attended chiefly by girls who have left school. In 1903 the University of Lyons offered a two years' course to women, six hours a week, on applied biology, bacteriology, the rôle of women in the family, hygiene, etc. The subject is slowly gaining recognition in the primary schools of Paris, chiefly in connection with the *cantines scolaires*, for which the elder girls prepare the food. No provision is made for the adequate training of teachers. Great credit is, however, due to the work of *La Ligue Patriotique des Françaises*, for the promotion of such teaching as does exist among women of all ranks in France.

**Italy** — The state and municipal recognition and support now accorded to the domestic arts is due to the influence of Queen Margherita at the end of the nineteenth century, as well as to that of the venerable "apostle of training in the domestic arts," Signora Adèle Levi Della Vida. The parent institution of the numerous *scuole professionali* established at Rome, Turin, Venice, Milan, Florence, Naples, Parma, Bologna, Palermo, etc., for boys and girls of the working and artisan classes, was started by the municipality of Rome in 1876. The Minister of Public Instruction (Signor Boccechi) introduced manual instruction into the primary schools in 1889, the teaching of housewifery followed in 1904 and became obligatory in the *scuole professionali* in 1907. These schools aim, with every evidence of success, at the preservation of educational advantages, while stress is coincidentally laid on the acquisition of practical skill. Pupils are admitted, with a nominal entrance fee, at ten years of age, there to finish their elementary education and then to proceed to some special line of handicraft. All girls must learn drawing and cooking, while choice of three subjects must be made from needlework, lace, white embroidery, dressmaking, ironing, hairdressing, artificial flower making, geometrical and ornamental drawing and design, or bookkeeping, etc. The wages earned on leaving average double those of untrained girls. These schools are subsidized by the State and municipalities. Several schools for the training of matrons for factories exist in North Italy. Classes have been formed at Milan and other cities for the training of young girls of the working classes, while training for girls of the upper classes are provided at Rome in 1907. These private efforts receive state aid.

**Australia** — Cookery has been taught in

New South Wales since 1890, by 1905 both sewing and cooking had been introduced into the public schools. Centers to which children from neighboring schools are sent have been established throughout the State. The courses extend over one half year, with one meeting of an hour each week. The work is simple and practical, relating to duties of the home. Provision has been made for the training of teachers for the subject. In Victoria there are some twenty-five fully equipped centers for cookery throughout the State, the State is prepared to double any local expenditure for the erection of suitable kitchen and dining room. In Western Australia there is a similar system of centers attended by children from definitely assigned schools. The subjects taught are cookery, laundering, sewing, and housewifery. Perth is the first town in the commonwealth to establish housewifery and a complete cottage. Here cookery, laundering, care of sick, infants, and young children, besides house care and management, house furnishing, and decoration, marketing, and cleaning. In Queensland many branches of the subject are taught in the numerous technical colleges and in "branch classes" (extension) where no technical college exists.

**South America** — The girls of the upper classes are taught mainly in convents, in which the domestic arts include sewing, embroidery, flower making, and lace making. In the Argentine Republic there are so-called "professional" schools in which domestic science and needlework are taught. At Buenos Aires three trade schools for girls are maintained, while there is also a commercial school for women. Girls from seven to thirteen in the primary grades of Brazil have needlework. Higher work is provided in manual training schools, normal colleges, polytechnic schools, and schools of arts and trades. At Montevideo, Uruguay, some branches of household arts are taught in the school of arts and trades.

**Canada** — At present domestic science and art are taught in a great number of the large public school systems throughout the country, usually by peripatetic teachers. For advanced work provision is made in many agricultural colleges and special schools of household arts or science, the best known being the Macdonald Institute at Guelph, Ont., and the Macdonald College at Ste Anne de Bellevue, Que. (See CANADA, EDUCATION IN.) A. R.

**HOUSES, SCHOOL.** — See ARCHITECTURE, SCHOOL.

**HOUSTON COLLEGE, HOUSTON, TEX**  
— An institution for the education of colored men and women, established in 1845. Elementary, college preparatory, normal, industrial, and theological departments are maintained.

**HOVEY, CHARLES EDWARD** (1827-1897)  
— Normal school principal; graduated at Dartmouth College in 1852. He was principal of the High School at Framingham, Mass., 1852-1854, superintendent of the schools at Peoria, Ill., 1854-1857, and first principal of the Illinois State Normal School, 1857-1861. He was editor of the *Illinois Teacher*, 1856-1861.  
W. S. M.

**HOW, SAMUEL BLANCHARD** (1790-1868). — Sixth president of Dickinson College, was graduated from the University of Pennsylvania in 1810 and the Princeton Theological Seminary in 1813. He was president of Dickinson College from 1830 to 1832. He was the author of several works on religious education.  
W. S. M.

**HOWARD COLLEGE, BIRMINGHAM, ALA.** — An institution founded in 1842 under the auspices of the Alabama Baptist State Convention. Academic and collegiate departments are maintained. Ten units are required for entrance to the college, which grants the degrees of A B and A M. There is a faculty of thirteen members.

**HOWARD, JOHN** — See PENOLOGY, EDUCATIONAL ASPECTS OF

**HOWARD PAYNE COLLEGE, BROWNWOOD, TEX** — A coeducational institution under the control of the Baptist General Convention of Texas, founded in 1889. Preparatory, college, normal, business, music, expression, and art departments are maintained.

**HOWARD UNIVERSITY, WASHINGTON, D C** — A coeducational institution for all races. The university buildings, with the exception of the medical and law schools, stand on a campus of twenty acres. The institution maintains a college of arts and sciences, a teachers' college, a school of manual arts and applied sciences, an academy and commercial college, as well as the schools of law, medicine, and theology. The entrance requirements are fifteen units of work. The degree of A B is conferred on the completion of a college course or a four years' course in the teachers' college. The entrance requirements to the school of medicine are those of the Association of American Medical Colleges, and a four years' course is offered. The New Freedmen's Hospital affords

clinical facilities to the medical college. The school of law which is situated in the city offers a three years' course, the requirements for which are a four years' high school course. There are 121 members on the faculty

**HOWE, SAMUEL GRIDLEY** (1801-1876).

— Founder of American institutions for the education of the blind, was born at Boston on Nov 10, 1801. He was educated at the Boston Latin School and Brown University, graduating in 1821. Three years later he completed the course at the Harvard Medical School. He served for six years in the Greek war of liberation, and for a time gave his services to the cause of liberty in the ill-fated kingdom of Poland. At the suggestion of Dr. John D. Fisher he went to France in 1831 to study the methods of educating blind children, and in the following year he opened at South Boston the Perkins Institution and Massachusetts School for the Blind, and during the next forty-four years he trained the teachers and shaped the policy of practically all the schools for the blind in the United States. (See the article, **BLIND, EDUCATION OF**.) One of his notable triumphs was the education of Laura Bridgman (*qv*), a deaf-blind girl, and through her education the development of a system of touch training now widely used in the education of deaf-blind children. In 1846 he was chairman of a commission for the study of idiotic and feeble-minded persons, which resulted in the establishment of the Massachusetts School for Feeble-Minded Children. In cooperation with his wife, Julia Ward Howe, he founded the *Daily Commonwealth* in 1851. He originated the Massachusetts State Board of Charities and Corrections in 1863, — the first of its kind in the United States, — and was its first president. He was intimately associated with Horace Mann (*qv*), in the establishment of the Massachusetts common school system. He wrote numerous papers on the education of the blind and feeble-minded, several works on Greek modern history, and a number of textbooks for the use of the blind. W S M

**HOWELL, JAMES** (1594?-1666) — Historiographer Royal of England (1661), and educationally of importance from his interest in advancing the study of foreign languages both by study in England and by his advocacy of travel abroad as a means of education. He is now best known by his letters from abroad.

Howell was of a Welsh family, educated at Hereford Grammar School, whence he was entered at Jesus College, Oxford, and graduated B A in 1613. With foreign missions and secretariats he lived until 1642, when he was appointed as clerk of the Council, an arrangement upset by the Civil War. He turned to writing for a livelihood, and, as Mr. Arber says, "he is one of the earliest instances of a literary man successfully maintaining himself with the fruits of his pen."

In his *Instructions for Forreine Travel* (1642) he claims to show "by what course and in what compass of time, one may take an exact survey of the kingdoms and states of Christendom, and arrive to the practical knowledge of the languages to good purpose." In this short treatise he points out the educational use of travel, "which may be not improperly called a moving academy, or the true Peripatetic School." More direct contributions of Howell to educational progress are to be found in the direction of linguistics. (1) He published a new edition of the French-English and English-French *Dictionary of Randle Cotgrave* (*qv*) in 1650, adding his "Animadversions." The book is addressed to nobles and gentry, and to merchant adventurers both English and the "Dutch here resident" for commercial purposes. (2) The *Polyglot Dictionary* of Howell marks the highest development, up to 1660, of polyglot dictionaries, from the point of view of the English people. The comprehensive nature of the work was intended to meet the needs of nobles and gentry, of commercial people and of scholars. Howell not only produced his modern languages lexicon, but did for adages or proverbs generally in England what Erasmus had done for classical adages in Europe. Still further, he brought his native Welsh language in line with other languages as worthy of knowledge and study by other nations. (3) *Howell's Grammar: A New English Grammar, Prescribing as certain Rules as the Language will bear, for Forreiners to learn English.* There is also another *Grammar of the Spanish or Castilian Tongue, with some special remarks upon the Portuguese Dialect etc.* Whereunto is annexed *Discours or a Dialog containing a Perambulation of Spain and Portugall, which may serve for a direction how to travell through both Countreys, etc.* For the service of Her Majesty (i.e. Queen Catharine of Braganza) whom God Preserve 1662. This contains the English grammar on one page and the same rendered into Spanish on the other. Howell attempts "a grammar of English in itself," not an English grammar, "to learn another language as Lily for Latin and Littleton for French" (See **HOLYBAND**.) Accordingly (p. 83) Howell writes an account of *Divers superfluous letters in English Orthography*, and advocates phonetic spelling as much as possible, his maxim being *Frustra fit per plura quod fieri potest per pauciora*. F. W.

**HUARTE NAVARRO, JUAN DE DIOS** — Physician, psychologist, and educationist, born at Saint-Jean-Pied-de-Port, in Navarre (Basse-Navarre) about 1536. Though French by birth, he was Spanish by training. Huarte's name lives on account of his book, in which the mental activity brought to bear on the greatest educational problems affords ground for naming it one of the most remarkable original works issued by the press in the sixteenth century (1575). This work was translated from an Italian version by Richard Carew (*q.v.*) in 1594, with the title *Examen de Ingenios, The Examination of men's Wits*. In which, by discovering the varietie of natures, is shewed for what profession each one is apt, and how far he shall profit therein. By John Huarte Translated out of the Spanish tongue by Mr. Camillo Camilli. Englished out of his Italian, by R. C. Esquire. Insisting on the essential differences in individual abilities, Huarte points out that it is thus necessary educationally to make an examination or trial of minds to see the diverse natures or "wits" and from such an inquiry to determine the special directions from which they are to find suitable nutriment in the material of knowledge.

Huarte suggests classification of pupils on the basis of temperament or of psychological characteristics, rather than on common possession of the same details or bulk of knowledge; and claiming the authority of Galen, Huarte would wish state officials to sound the wit and

natural application of children so as to set each to learn the art most suitable to each, and "not leaving it to them to act of their own choice." There is much that may be regarded as antiquated about Huarte's views of temperament and the soul in its three aspects. But Huarte is certainly in accord with later educational writers in his emphasis on self-activity as the principle of the human soul, in his theory of the effect of climate on character, in his idea of heredity and the influence of dieting on temperament and thence on educational processes. Huarte also takes up questions of parentage, on the physical side, discussing the birth and prenatal conditions of "wit" in children.

Huarte has taken ideas from Plato, and still more from Aristotle. Yet his debt is greatest of all to Galen (see Dr Guardia's *Essay*, p 253). Huarte cites from classical authors and from the Scriptures in the manner of post-Renaissance writers. Dr Guardia has given a full account of the critics of Huarte.

Besides Richard Carew's translation in 1594, another was undertaken in 1698 by Edward Bellamy, who describes the book as "useful for all Fathers, Masters, Tutors, etc." It will thus be seen that the suggestions of Huarte logically led to the advocacy of child study, and he deserves recognition as one of the most important of the pioneers of the subject.

Huarte was adversely criticized by Antonius Possevinus e Societate Jesu, *Cultura Ingeniorum*. . . *Examen Ingeniorum Io Huartis expenditur* (which first appeared in Possevinus's, *Bibliotheca selecta de ratione studiorum*, Rome, 1593; and afterwards was separately published, e.g. 4th ed, Venice, 1604), and by Jourdain Guibet (Docteur en Médecine), *Examen de l'Examen des Esprits* (Paris, 1631). F. W.

**HÜBNER, JOHANN** (1668–1731). — German schoolmaster and author of textbooks in scripture, history, and geography. He graduated at Leipzig, and for a time lectured there, in 1690 he became rector of the gymnasium at Merseburg, and in 1711 rector of the Johanneum at Hamburg in succession to Fabricius (*q.v.*). His success, however, lay more in his textbooks, especially *Kurze Fragen aus der alten und neuen Geographie* and *Zweimal zwei und fünfzig auserlesene biblische Historien und Fragen* (1714). Both works were translated into many foreign languages, and the

latter at any rate had a great vogue for many years. The biblical stories were short, and Hubner's method was to have pupils read them two or three times and then be ready to answer questions on the text. Hubner's book furnished the questions without answers. Hubner also issued a number of school atlases and maps. Just before his death he published *Die ganze Historie der Reformation in funfzig kurze Reden nebst einem Schauspiele von Bekehrung der Sachsen zum Christentum* (The complete history of the Reformation in fifty brief Addresses, with a Play on the Conversion of the Saxons to Christianity, 1730).

**HUE**—This term refers to the specific qualitative difference between colors, which may, however, possess equal saturation (*q v*) and brightness (*q v*). The *hue* and the *tone* of a color are distinguished by reserving the latter term for monochromatic lights (see **COLOR**), while "hue" refers to mixed lights as well. Thus, red, yellow, blue, etc., are tones, scarlet, purple, crimson, etc., are hues. Buff and yellow, lilac and lavender, on the other hand, would not differ so much in hue as in saturation, or, to use the artist's terminology, in chroma.

R. P. A.

**HUGH OF ST VICTOR** (1096-1144) — A twelfth-century scholastic theologian, philosopher and mystic; was born at Blankenburg in the Harz, and at an early age took the habit of the Canons Regular of St. Augustine at Hamerleve, near Halberstadt. There he received his early education. In 1115 he went to the house of his order, the celebrated monastery of St. Victor, near Paris, where the entrance seven years previously of William of Champeaux marked the foundation of the Victorine School of mysticism. From 1133 to his death in 1144, Hugh was head of the school. Besides works on general theological subjects and on sacramental theology which earned him the title of *Alter Augustinus*, he wrote a number of important treatises on mystical theology, namely, *De Arca Noe Mystica*, *De Arca Noe Morali*, *De Vanitate Mundi*, *De Arrha Animæ*, *De Amore Sponsi ad Sponsam*. These are published in Migne's *Patrologia Latina*, Vols CLXXV-CLXXVII.

As a mystic, Hugh did not go to the length of condemning all rational philosophy. On principle, he avoided the discussion of questions which, though they occupied almost exclusively the minds of his contemporaries, seemed to him to be futile. Such, for instance, was the question of Universals. He himself, especially in the work *Eruditionis Didascalæ*, developed a system of philosophy in which he

attached paramount importance to psychological introspection. But while he appreciated philosophy, he maintained that all rational knowledge must be supplemented, and in a sense superseded, by mystic contemplation. He taught that knowledge is not to be valued for its own sake, but as a means of attaining a contemplation of higher spiritual truths. In the treatise *De Contemplatione et ejus Speciebus* (pub by Hauréau in 1859) he distinguishes three stages in the mystic life of the soul. The first is the preparatory stage, in which the soul by thought (*cogitatio*) seeks God in the material world, the second is the meditative stage, in which the soul by reflection (*meditatio*) seeks God in itself; the third is the contemplative stage, in which the soul by intuition (*contemplatio*) seeks God Himself. The faculties by which truth is perceived in these successive stages are called respectively "the eye of the flesh," "the eye of the intellect," "the eye of the contemplation." It was by means of this doctrine that Hugh exerted a very widespread influence among mystical writers and teachers all through the Middle Ages. W. T.

HASSARD, JOHN R. G. *Life of the Most Reverend John Hughes* (New York, 1866)

**HUGHES, THOMAS** (1823-1896) — Author of *Tom Brown's School Days*, born at Uffington, Berks., and educated at Rugby and Oriel College, Oxford. At Rugby he came under the influence of Thomas Arnold (*q v*), of whom he has drawn such a reverent picture in the story of the school. By profession Hughes was a barrister, but his interests were mainly in the social questions of the day. He took up the cause of trades unionism, cooperation, and the relations between employers and workmen.

He was intimately associated with F. D. Maurice (*q.v.*), the Christian Socialist movement, and the Working Men's College in Great Ormond St., London. Here he conducted a Bible class, out of which came his work, *The Manliness of Christ* (1879). He was principal of the college from 1872 to 1883. His interest in social reform influenced him to enter politics, and from 1865 to 1874 he sat in the House of Commons. His admiration for Lowell prompted him to visit New York and Boston, where he was received with enthusiasm as the author of *Tom Brown's School Days* and as a sympathizer with the North during the Civil War. In America, too, at Rugby, Tenn., he established a colony on a cooperative basis, which, however, was financially a failure.

In addition to *Tom Brown's School Days*, which he wrote in 1853 and published anonymously in 1857, Hughes was the author of *Tom Brown at Oxford* (1861); *The Scouring of the White Horse* (1889), *Memoir of a Brother* (1873), *Vacation Rambles* (1895). But his fame will always rest on *Tom Brown's School Days*, which, more than any other work, spread far and wide the fame of Rugby, the reforms of Arnold, and the spirit of the public school. For some time it was thought that the prototype of Tom was Hughes himself or his elder brother, George, and that Arthur was Dean Stanley, but the author denied this strongly in the preface to *Tom Brown at Oxford*.

**HUMANE EDUCATION.** — This form of education is a product of the humane movement of the past century, which began in a distinctive way in England in 1822 with the passing by Parliament of the first law for the prevention of cruelty to animals and with the organization of the Royal Society for the Prevention of Cruelty to Animals. In the United States its beginning was marked by the organization of the American Society for the Prevention of Cruelty to Animals in 1866. The movement has since spread so rapidly that organized protection of animals against cruelty and neglect is now world-wide.

The term "humane education" might fittingly be applied to any effort aimed at the inculcating of humane ideals or the furthering of humane practices by precept or rule of action. Such effort would include at least three aspects: (a) the instruction of children along humane lines, (b) the educating of teamsters and others dealing with animals in best methods of care and treatment, (c) the forming and

stimulating of public opinion — through press and pulpit, through special literature and through exhibitions — to a more humane attitude and practice. Only the first of these phases will be dealt with here.

The philosophy underlying humane education varies among its advocates. As a rule the basis is emotional rather than rationalistic. This basis finds its most consistent expression in the view of an equality of absolute rights on the part of all sentient creatures. It is regarded as a mistake to suppose that the rights of animals are in any way antagonistic to the rights of men. Animals, as well as men, in this view, have the right to live a natural life, to attain an individual development, subject to the limitations imposed by the permanent needs and interests of the community. And in determining what these permanent interests are, there should be equality of claim on the part of all orders of animal creation. This is a philosophy of individualism applied to all sentient life. Another view, that may properly be contrasted with this, would take into account the desires and pleasures of the inferior animals, but not from the standpoint of the positive rights of the animals themselves. Man's sovereignty over the animal kingdom is recognized, and the effects of man's acts upon human character and welfare is viewed as a dominant consideration. Rights are relative. The rule of nature is that the lower generally serves the ends of the higher. The question of suffering and destruction inflicted by the stronger upon the weaker should be made a subject of scientific study as well as of sentimental regard. In any scheme of humane instruction, the sympathy of the young is the motive that forms its cornerstone. With the philosopher of absolute rights the major aim is to arouse that sympathy by dwelling on cases of extreme cruelty and suffering, to reach a humane attitude by developing a keen appreciation of wrongful acts. The relativist, on the other hand, tends to lay stress on a knowledge of the structure, habits, and functions of animals. What ought to be done, rather than what ought not to be done, is emphasized, and a cardinal purpose is to teach that unnecessary and wanton injury or destruction of either plants or animals is uneconomical, injurious to society, and dangerous to the character of the offender. Actual instruction along humane lines, however, is ordinarily based on no well-reasoned philosophy of animal treatment. The mass of those associated with the anti-cruelty movement are not doctrinaire. They simply follow the opportunist policy of dealing with cruelties as they arise, and of mitigating severities of animal treatment as far as the prevailing situation will permit. Humane educational schemes usually share this opportunist quality.

*Private Organization* — For the most part, humane education is carried on under private

auspices Humane workers have steadily emphasized the need of humane instruction in public schools, and some progress has been made in this direction, but the larger effort has been expended on instruction given in small groups, organized in any opportune way. Various titles are given to such groups. "Junior Humane Society" is sometimes applied, "Young Defenders" is the name used in the parent American anti-cruelty society, but "Band of Mercy" groups are much the most numerous, and their activities are typical of scope and method, by whatever name children's organizations of this sort may be known. The first Band of Mercy was established by Mrs. Caroline Smithies at Wood Green, England, in 1875. At her death the movement was continued by her husband and daughter, and later, in 1883, a union of all bands in the kingdom was formed, with the Royal Society for the Prevention of Cruelty to Animals at the head. Under the arrangement the Royal Society became the governing body for the union, but the bands retained their freedom of direction and responsibility in all local matters, including financial independence. Uniform cards of membership, members' badges, and registers were adopted by all bands. The governing body provided these at cost. A half-penny monthly journal, previously and since issued by the Royal Society, entitled *Band of Mercy*, became the organ of the union. The bands have multiplied in number. Their formation has been promoted in many directions, as separate and distinct organizations, or within Sunday or day schools, or in connection with Bands of Hope or other moral, social, or religious associations. The Royal Society has been particularly insistent that each band should have a formal organization and a permanent secretary. Members pay small dues. Regular meetings are held at which lectures or addresses are given, Band of Mercy melodies sung, readings and recitations delivered, stories and anecdotes related, and interesting or meritorious work done by members reported.

The pioneer in American Band of Mercy work was Mr. George T. Angell of Boston. He founded the American Humane Education Society, which has been instrumental in forming more than eighty thousand such bands in the United States. How many of these are active organizations it is impossible to say. To each band of thirty or more members the Society sends each month a copy of *Our Dumb Animals*, from which readings and recitations may be selected. *Twelve Lessons on Kindness to Animals*, published by the Society, badges, members' cards and other matter are likewise provided. Effort is made to have Band of Mercy Day observed in the public schools. In Massachusetts a day in April has been observed in this way for three years past, and in the schools of Boston for four years. In 1909 a pamphlet of thirty-two pages, the *Humane*

*Manual*, was gratuitously distributed to the 15,000 teachers of the State. In 1908 a similar pamphlet containing a reprint of selections from the chapter on animals in Hyde's *Practical Ethics* was so distributed. This work is in the hands of the State Organizer of the Society.

An interesting experiment along these lines has been undertaken in New York by the American Museum of Natural History. A series of lectures dealing with animal life were planned to be given at the museum and at various settlement houses throughout the city. The lectures were used as a starting point for the formation of settlement bands of "Young Defenders," who are expected to protect street dogs and stray cats from molestation and to report cases of ill treatment to the anti-cruelty society. Another method of reaching children is that of instituting humane essay competitions in schools, to the winners of which suitable prizes are awarded. In Buffalo, for instance, more than 1500 such essays were received from pupils in the sixth, seventh, eighth, and ninth grades and high schools in the 1909 competition. In Rochester the Humane Society offers prizes to public, private, and parochial schools in a similar way.

Even in a hasty survey of private efforts for the humane education of children, it would be a mistake to leave the impression that its object ends with the attaining of a more kindly attitude toward dumb creation. Its material in the main deals with animals, and is calculated to further their humane treatment, but its aim — however quixotic and inspirational its methods — is the broader one of developing a more considerate attitude in every aspect of life.

*State Provisions* — State legislation has done little to further humane education, beyond recognizing humane societies, Audubon societies, and other organizations as agencies for its promotion. A succession of New York laws provide for an agreement with the American Museum of Natural History in New York City, by the terms of which materials, specimens, etc., are provided for free instruction in natural history in normal and other schools for the preparation of teachers, and in free common schools. Further, lectures are provided for, to be given on holidays and at other suitable times to artisans, mechanics, and other citizens. In Illinois, California, and some other states the law provides for an annual "Bird Day" in the schools. The law of Colorado requires that two lessons per week (not less than ten minutes each) be given in the schools on the humane treatment of animals. The law of North Dakota prescribes a like period for "a system of study of the humane treatment of animals," as do the laws of South Dakota, Montana, and Wyoming. The latter three, however, specify "a system of humane treatment as embodied in the laws of

## HUMANE EDUCATION

the respective States, and do not prescribe a definite period of instruction. In California humane education is compulsory in all primary and grammar schools having more than one hundred census children in the district. This instruction may be oral, and the purchase of textbooks may not be required of pupils. In Oklahoma the law prescribes instruction in schools to the amount of not less than one half hour per week on the "humane treatment and protection of dumb animals and birds; their lives, habits, and usefulness, and the important part they are intended to fulfill in the economy of nature." The Illinois law is similar, but is the most extended of any of the state laws. The Pennsylvania law provides for not more than one half hour per week on the "kind treatment of birds and animals," and those of Maine and Washington for not less than ten minutes. The law of Texas prescribes that "suitable instruction shall be given in the primary grades once each week regarding kindness to animals of the brute creation and the protection of birds and their nests and eggs." The New Hampshire statute provides for "a well prescribed reading course dealing with the principle of the humane treatment of the lower animals." Idaho and Utah have been reported as having compulsory requirements.

In England, France, and Germany, humane education is in no degree compulsory, although in all varying effort is made to link up private humane effort with the work of the schools. Literature is given to pupils and teachers, teachers' conferences are held, and other devices are employed similar to those used in the United States. In France activities have perhaps been more systematic and effective than in the other countries. Humane instruction there finds a place in the schools incidental to the general scheme of moral and civic instruction. More than six thousand *Sociétés Protectrices* have been formed in the schools under the patronage of the national society for the protection of animals. The English *Code of Regulations for Public Elementary Schools* contains a note to the effect that instruction "should be especially directed to the inculcation of courage, truthfulness, cleanliness of mind, body, and speech, the love of fair play, consideration and respect for others, gentleness for the weak, kindness to animals," and other considerations. But English humanitarians lament their failure to carry out this suggestion in specific ways.

## HUMANISM AND NATURALISM

- SALT, H. S. *Animals' Rights*. Humanitarian League (London, 1905.)  
 WHITEHEAD, E. K. *Dumb Animals and How to Treat them*. (Chicago, 1910.)

**HUMANISM** — See COURSE OF STUDY, THEORY OF; CULTURE; HUMANITIES, LIBERAL EDUCATION, RENAISSANCE AND EDUCATION.

**HUMANISM AND NATURALISM** — In educational literature, humanism has usually a specific meaning, indicating a distinctive intellectual tendency that marked the revival of learning in the fifteenth and sixteenth centuries. For that aspect of humanism, see RENAISSANCE AND EDUCATION.

Under the present caption, only a somewhat rarer and also looser signification of the term, belonging to certain problems in the philosophy of education, receives consideration. From the side of educational practices, this philosophical question originated in the just mentioned historic sense of humanism. As a consequence of the revival of learning (along with the backward state of the natural sciences), linguistic and literary culture succeeded theology as the controlling factor in higher education. By the nineteenth century, however, natural science had made such extraordinary advances that its representatives were naturally restive, and even rebellious. They challenged the practical supremacy of language and literature, and attacked on intellectual grounds the theories that were advanced in justification of this supremacy. Upon the practical side, the case was decided in favor of the claims of the natural sciences—not, of course, that the humanistic studies were excluded, but that the claims of scientific study were admitted upon substantially equal footing, whether by insertion of some natural science into the old classical course or by affording students an option between a literary and a scientific course. The adjustment thus far reached represents, however, a working compromise through concession to forces strong enough to force recognition, rather than a solution based upon any generally recognized philosophy of the relations of man and nature to each other. As ideals humanism and naturalism are perhaps more sharply opposed to each other now than at any previous period.

Humanism may be defined as the conviction that spiritual and ideal values are of supreme rank in the make-up of reality, and that these values are most adequately expressed in the great or classic achievements of humanity in literature and art—especially literature. Naturalism rests upon the conviction that, negatively, humanism is a survival of the geocentric medieval philosophy, with its false conception of the place of the earth and of man in the universal scheme, and with its exaggerated teleological interpretation of things; positively, that man and his affairs are a subordinate part of nature, seen in their true place

only when nature is made the chief and primary object of study. Incidentally, naturalism almost always has as one of its implications that language and literature are too artificial, factitious, and, as it were, ornamental, to be a sound basis for education. Science, it is urged, presents mankind with truths concerning realities of existence, language and literature with man's accidental and fanciful reactions to these realities.

Philosophically viewed, the controversy is a reflection of the time-worn discussion of the relations of spirit and matter, mind and nature, subject and object; and the supposed antagonism of naturalism and humanism originates in dualism (*q v*) respecting these concepts. Greek classic philosophy presents, upon the whole, a view of things in which there is a balance between naturalism and humanism. From one standpoint, that of value, a humanistic idealism dominates; the life of reason as exhibited in the realization of distinctively human functions is the supreme moral good, and hence the ultimate measure of worth in education. This conception was embodied in the Aristotelian conception of a *liberal* education and in the notion of the liberal as distinct from the mechanical and industrial arts. But reason is not a peculiar and isolated property, much less creation, of man. On the contrary, nature, in virtue of its orderliness, and especially in view of the fact that its order shows itself in the tendency to achieve specific ends, is itself rational, and the attainment of rationality by man is nothing but the realization in conscious thought of the relations immanent in nature. From the side of conditions or efficient means nature also, not man, is supreme. The values, or goods, of life are absolutely dependent for their achievement upon the efficacious workings of physical conditions, even the contribution of human deliberation and effort, regarded as a causal factor, falls within the scope of nature. Or, as Aristotle puts it, mind is the actualizing, the complete energizing, of the body, a view which makes it impossible to regard mind as a separate independent causal force. In short, classic Greek idealism was idealistic in the sense that it had a teleological view of nature. Nature and mind were not regarded as two forces working either together or against each other, but as means and end, causal conditions and final values, potentiality and actuality.

Medieval philosophy, even when professedly following Aristotle, introduced two profound modifications into this view. On the one hand, nature as it now exists is fallen or corrupted, being implicated in "an aboriginal catastrophe," the denial by the first man of God's will as law, and the substitution for it of human inclination. This profound perversion of reality affected all physical nature, in itself completely good, as well as human nature. The inevitable result (taken of course in con-

nection with the barbarous state of society) was a depreciatory attitude toward all knowledge of a natural kind, in contrast with knowledge having to do with man's redemption — the subordination, both in philosophic theory and educational practice, of natural knowledge to supernaturally revealed science, or theology. Medieval philosophy also inverted the relation between mind and nature, for it regarded mind as the sole ultimate *efficient* cause of natural existence, instead of conceiving mind as the *final* cause, or good, of natural things. Thereby a metaphysical dualism of spirit and matter was superadded to moral dualism of the first state and ultimate destiny of man as contrasted with the present state of nature.

Renaissance philosophy was humanistic in both the narrower and the wider sense of that term. It found in the revival of Greek philosophic thought a means of justifying the growing interest in the phenomena of physical and human nature. Like Greek thought, it rested in a conception which united humanism and naturalism. Naturalism was opposed to supernaturalism, and hence represented the means of satisfying distinctively human, instead of theological, potentialities and aims. The prevailing way of conceiving the relation of man and nature was that of a microcosm to a macrocosm. Man was in small edition that which the universe was in large. As Windelband truly says, the natural science of the seventeenth century was the daughter of the humanism of the sixteenth century.

This union, resting upon the use of Greek thought and the emulation of the free Greek spirit to justify a free and full satisfaction of human capacity through natural conditions, was, however, soon undermined from both sides. Humanism became more technical, more literary and philological, and less philosophical. Moreover, the rise of the Protestant-Catholic controversy diverted the study of language and literature from social and æsthetic channels, and made its use a weapon of religious dispute. As natural science worked itself free from the earlier mystical and imaginative traits, it became more and more purely mechanical, more and more indifferent to teleological considerations. Nature mechanically viewed is indifferent to mind, or even opposed to it, since the chief mark of mind is its purposiveness. This tendency of natural science toward dualism was reinforced by the growing moral and political interest in the self or ego, and by the development of the idea that the final source of certain knowledge (as against the authoritative impositions of dogmatic beliefs), was to be sought simply within the inner self, the field of personal consciousness. These two latter factors conspired with the discovery of the "inner world" as a field for literary exploitation, to mark off mind, reason, as a realm by itself, sharply contrasted with nature. Natural and mechanical science was concerned

with the "object," and over against the object stands the "subject," defined and described in terms exactly antithetical to those applicable to nature, or the object. The resulting dualism motivates directly all the philosophic problems of the seventeenth century, and supplies the background of the controversy between naturalism and humanism in education.

The difficulties and problems that arise in rigid philosophic dualism are paralleled in educational controversy. By assumption, there are two separate words, and yet both of them are necessary to make up the whole account of our real experience. The result is, inevitably, whether in pure theory or in educational, a mechanical compromise assigning one isolated region to mind and humanistic study and another to matter and to naturalistic studies. The same forces, however, that have tended to break down the rigid dualism of mind and matter have operated, though independently, to render questionable the division of studies into exclusively human and exclusively physical. The rapid development of the historical, anthropological, economic, and other social sciences has introduced a large and important body of material that will not fit easily into either of the older rubrics. Obviously humanistic in matter and import, it also emphasizes both in its subject matter and its methods of explanation processes that connect man's life with natural conditions. The theory of evolution when applied to humanistic subject matter tends also to bring out its continuity with natural conditions. Industrial conditions are seen to have the most intimate bearing upon human affairs, and they also are bound up with the natural sciences. As long as economic affairs were regarded as out of the pale of serious concern by all those occupied with man's higher interests, it was an easy matter to side-track them intellectually and educationally. Now that the close connection of economic conditions with success in attaining the highest political and moral status of society is generally recognized, the thinness and superficiality of a humanism that excludes from attention all reference to industry, commerce, and applied science become increasingly obvious. As a consequence, contemporary philosophy and contemporary educational theory may be said to be confronted with a common problem: The discovery of the common background or matrix in which humanistic and naturalistic interests are united, and the tracing of their respective differentiations from this community of origin,—a differentiation, however, which should not become a separation, and which, accordingly, secures the possibility of fruitful interaction between them whenever desired.

**HUMANITIES, THE.**—This term came

into use in the fifteenth and sixteenth centuries as an English equivalent of the Latin *literæ humaniores*, meaning in effect literary culture, "letters." The sense of the term was probably influenced by reminiscence of the use of the word *Humanitas* by Aulus Gellius and Cicero to denote the liberal culture befitting a man as a man. It was influenced by a differentiation from "divinity," so as to designate the studies of human interest as distinct from the theological studies which had dominated medieval education—especially to designate secular instead of "sacred" rhetoric, poesy, and grammar. This wider sense of the term shaded naturally into a narrower one. Since as a matter of fact the material of literary secular culture was at first the Latin, and then the Greek languages and literatures, the term "humanities" came to mean almost exclusively the study of Latin and Greek. Humanity is still in use in the Scottish universities as a technical term for the study of Latin, and at Oxford the classical studies are known as *literæ humaniores*. Generally speaking, in the seventeenth century a humanist meant a grammarian or philologist. In the nineteenth century the use of the term was influenced by the conflict in higher education between the classical studies and the sciences of nature. In the course of the controversy, the term tended to broaden its meaning, and to revert to designating whatever concerns man as distinct from physical nature.

**HUMBOLDT, FRIEDRICH WILHELM CHRISTIAN CARL FERDINAND VON** (1767-1835)—The German philologist and statesman in his short connection with the educational administration of Prussia exercised a strong influence on its future development. A profound scholar himself, he readily seized the opportunity afforded by his position to introduce the characteristic features of the New Humanism. (*qv*) into Prussian higher education. But from another direction, too, his strong faith in independence and self-activity led him to introduce much-needed reforms in all branches of education, so that in the universities the spirit of academic freedom was given the greatest scope, while in the elementary schools the Pestalozzian methods and the encouragement of individual development found a strong advocate in Humboldt. Educated privately by skillful teachers, he later attended the universities of Frankfurt-a-O,

Göttingen, and Jena, interested above all in the humanities and especially in Greek culture. In 1790 he entered the Prussian civil service, but retired within a year. In 1802 he was appointed minister to the Vatican, where his duties did not prevent him from forming a circle of friends interested like himself in classical studies. In 1808 he became Privy Councillor and Director of Ecclesiastical Affairs and Public Instruction, an office which he held for about eighteen months. In this brief period he instigated the reorganization of the system of admission to the universities which resulted in new regulations for the *Abiturientenprüfung* (qv). An important step in advance was made by the introduction of an examination for secondary school teachers. Hitherto appointments were made locally, and the candidates were as a rule students of theology or clergymen. Humboldt desired to establish a secular teaching profession. The examination of teachers was placed in the hands of a commission which should also consider educational methods and systems, new curricula, textbooks, and other publications. To reform elementary education young men were sent to Yverdon to study Pestalozzi's work, while through Humboldt's influence Zeller was enabled to open a normal school at Königsberg, based on Pestalozzian principles. Humboldt himself evinced an interest in the teaching of drawing and music. The whole work of Humboldt was directed to raising the cultural standards of the nation and to give it a feeling for the beautiful and æsthetic. In 1810 Humboldt retired from educational administration, but in the interval up to his complete severance from political life in 1819 he held several important posts which required delicate diplomatic ability.

As a scholar Humboldt ranks high in the field of philology. He established a reputation as a critic by a review of Goethe's *Hermann und Dorothea* in 1800. His chief works were, however, in linguistics, the principal of these being: *Prüfung der Untersuchungen über die Urbewohner Hispaniens vermittelt der baskischen Sprache* (*Researches into the Original Inhabitants of Spain by means of the Basque Language*, 1821), and *Über die Verschiedenheit der menschlichen Sprachen und ihren Einfluss auf die geistige Entwicklung des Menschengeschlechts* (*The Heterogeneity of Languages and its Influence on the Intellectual Development of Mankind*, 1836), a treatise on the philosophy of speech and language as the peculiar expression of a people's characteristics. His works were published in seven volumes (*Gesammelte Werke*) in 1840-1852, and under the title *Gesammelte Schriften* in 1904-1908. For portrait, see p. 586.

**HUME, DAVID** (1711-1776) — The philosopher; born and died in Edinburgh. Hume's works include *A Treatise of Human Nature*, *An Inquiry concerning Human Understanding*, *A Dissertation on the Passions*, *An Inquiry concerning the Principles of Morals*, *Political Discourses*, *History of England*, *Dialogues concerning Natural Religion*, essays on *Suicide*, the *Immortality of the Soul*, *Miracles*, *A Particular Providence and a Future State*, various other *Essays Moral and Political*, and a short autobiography. He left no strictly educational writings, and his influence on the history of education was so indirect that it is impossible to estimate its amount. But in psychology, ethics, metaphysics, history, religion, and economics his influence has been very great indeed. In psychology and metaphysics he carried through the prevailing doctrines of Locke (qv) and Berkeley (qv) with unrelenting logic to conclusions so repugnant to common sense that (as he fully realized) neither he nor anybody else could really believe them. Taking his cue from Berkeley's doctrine that we can form no conception of any material substance beyond our own ideas, such as these are usually supposed to reveal, he proceeded to prove that neither can we form any conception of a mind or any other reality behind them, such as they are usually supposed to belong to. Thus he resolved one's very self into "nothing but a bundle or collection of different perceptions (*i.e.* thoughts and feelings) which succeed each other with an inconceivable rapidity, and are in a perfect flux and movement."

This doctrine of the self is one example of the general philosophical "skepticism" in Hume which aroused Kant to write his *Critique of Pure Reason* and stirred Thomas Reid and his Scottish followers to develop the philosophy of "common sense," all more or less unsuccessful attempts to solve the problem of the possibility and nature of knowledge. Neither British nor German philosophy can be fully understood without a knowledge of Hume.

Hume's doctrine that a cause is practically nothing more than a uniform antecedent, and need not in any way resemble or be "greater" than its effect, has helped us to break away from a vast amount of medieval philosophizing, and prepared the way not only for the agnosticism of Huxley and Spencer, but for a genuine philosophy of evolution. In ethics and economics Hume clearly enunciated the principles afterwards worked out so successfully by his younger friend Adam Smith. Hume's *Essay on Miracles*, intended to be "an everlasting check to all kinds of superstitious delusions," did not attempt to prove that miracles cannot happen, but only that no amount of testimony is sufficient to prove one. Our only reason for believing in testimony at all is our experience of its truthfulness — of the usual or uniform conformity between a man's statements and the facts he tells about. But we mean by a

miracle a violation of the laws of nature — a single event contrary to the uniform experience of all mankind. To adduce the strongest kind of testimony for a miracle is therefore only to pit one experience of uniformity against another. The very thing that makes us trust the witness makes us disbelieve his tale. But in fact the testimony usually adduced for miracles is not strong at all. The witnesses are not usually trained observers, and they are influenced by religious enthusiasm and our common love of wonders. "Miracles" are commonest amongst ignorant peoples; and the more you believe in the miracles of any one religion, the more you must discredit those of every other. Hume's argument concerning a future state is somewhat similar to that concerning miracles. If we happen to believe in such a state, well and good, but the fact that things are not altogether as they should be in this world does not *prove* that they will be better anywhere else. In these two essays Hume shows the influence of his historical training. In the *Natural History of Religion* he discussed historically the probable origin of popular religious beliefs. H. A. A.

**HUMPHREY, HEMAN** (1779-1861) —

Second president of Amherst College; was born at Hartford, Conn., on Mar. 26, 1779. He was instructed by private tutors, and was graduated from Yale College in 1805. For several years he served as pastor of Congregational churches. He was president of Amherst from 1823 to 1845. He proposed the establishment of a department of education in the college for the training of teachers, but the proposition was never carried into effect (see EDUCATION, ACADEMIC STUDY OF, in the United States). In 1838 he traveled in England, France, and Belgium for the purpose of inspecting educational institutions. He was also active in the cause of temperance. His published writings include numerous addresses on education, an edition of the New England Primer, and a work on *Domestic Education* (1840). W. S. M.

**HUMPHREY, or HUMFREY, LAURENCE**

(c. 1527-1590) — Writer on the education of nobles in the time of Queen Elizabeth, was educated at Cambridge and at Oxford, was B.A. in 1549, and, becoming M.A. in 1552 from Mag-

dalen College, Oxford, lectured in that college on natural philosophy and on moral philosophy. In 1553 he joined the Protestant exiles in Basle, and then in Zürich, and afterwards at Geneva. In 1560 he was made Regius Professor of Divinity in the University of Oxford, and in 1561 he was chosen president of Magdalen College, Oxford. Humphrey was permeated with the Calvinistic views in religion, acquired abroad, and, as Anthony à Wood says, "did not only . . . stock his College with a generation of Nonconformists, which could not be rooted out in many years after his decease, but sowed also in the Divinity School . . . seeds of Calvinism, and laboured to create in the younger sort . . . a strong hatred against the papists."

Humphrey's chief educational work was entitled *The Nobles, or Of Nobility*. It was first published at Basle in 1560, in Latin, as *Optimales, sive de Nobilitate, eiusque antiqua origine, natura, disciplina*. His own English translation appeared in London in 1563, as *The Nobles or of Nobility. The Original nature, duties, ryght and Christian Institution thereof*. Joined with it is an English translation of the *Lytle Treatyse of Philo a Jewe, concernynge Nobility*. Humphrey's *Nobles* is dedicated to Queen Elizabeth and also to the Right Honourable and Worshipful Gentlemen of the Inner Temple.

Humphrey lays down the demand that the Nobility ought to learn and to give ear to wise counsels. He recalls the names of previous writers on the subject, Lucas Gauricus (Bishop of Civitate), and Hieronymus Osorius, and stoutly defends the distinction of classes as against Anabaptists and others. At the same time Humphrey declares that as to an "idle" Noble, he allows him "not so much as one inch of Nobility." Christ is the fane and type of Nobility. Nobles must "believe soundly and live uprightly," and have piety toward their country, a congenial topic for the Elizabethan age. They must be "liberal," a quality most proper to noblemen, and this liberality must be shown towards the learned. To these the nobleman's chest should be open. Similarly, he must be "liberal" to God's saints, and hospitable toward strangers. Justice must characterize the noble in all his dealings. With special regard to "institution" or education, it is the duty of the nobles themselves to cultivate virtues. Temperance must be cultivated. Sports are to be in moderation; and only for the purpose of making men manlier. But learning is a pursuit worthy of the Noble, and Humphrey declares he will give not merely his own opinion, but describe the "ancient princely way" of education. A learned careful teacher is necessary even for the elements. Grammar should be learned "briefly." The shortest of Cicero's *Epistles* follow. Then Dialogues, e.g. those of Erasmus (*q.v.*), and Castalio (*q.v.*). Terence must be

taught for his colloquial phrases, but with care that nothing undesirable be acquired from him. Even at first Greek and Hebrew should be learned ("preposterously do all Universities, schools and teachers that contrary it")

Another book by Humphrey, of considerable importance in its age, was the following *Interpretatio Linguarum. seu de Ratione convertendi et explicandi autores tam sacros quam profanos, libri tres* Basileæ, 1559. F. W.

**Historical**—The educational history of Hungary hardly begins before the influences of the Reformation made themselves felt in the sixteenth century. Stephen I, it is true, had as early as the eleventh century ordered the establishment in every parish of schools for the teaching of religion and reading, but the decree had little permanent effect. In 1854 the diet ordered that the funds of the despoiled monasteries should be used to create schools, and by this action stimulated the Catholic Church to new educational activity. But placed between the Turks and the Austrians, the Hungarians had little opportunity for development in the sixteenth and seventeenth centuries. After the crowns of Hungary and Austria were united in 1689, the educational history of the two countries developed along similar lines until the nineteenth century. A wholesome rivalry continued between the Protestant schools and Jesuit colleges until the suppression of the latter in 1772, and under the protection of Maria Theresa the national spirit was fostered without interference. In 1777 the *Ratio Educationis*, a Hungarian edition of Felbiger's (*q.v.*) Austrian regulations, was promulgated, but, since it identified education with the Catholic Church, was refused recognition by the Reformed Church. The anti-national measures of Joseph II, including the exclusive use of the German language, aroused so much opposition that they were withdrawn in 1790, with the exception of the freedom of worship. Before the close of the eighteenth century, the distinctive

features of Hungarian nationality, pride of language, and the spirit of religious and social toleration had been wrought into the schools.

The doctrines of the French Revolution of 1789 found ready sympathy in Hungary, but its manifestation was checked by the Napoleonic conquests. The deeper movement of 1848, which swept over all western and central Europe, revived the spirit of Hungarian patriots, and, led by Kossuth, they achieved momentary independence. The Estates of the Realm were replaced by a national assembly, and the draft of an elementary education law, conceived "in a modern and national spirit," was drawn up by Baron Joseph Eotvos, the first Hungarian Minister of Education. The effort was ended by the disastrous War of Independence, and the absolute rule that followed destroyed the legal basis of the old school system. No other was adopted until the reorganization of the Empire after the brief war with Prussia, which ended in the defeat of Austria in the decisive battle of Sadowa. By the compromise of 1867, Austria and Hungary became two distinct states under a common sovereign, and the same year the Emperor of Austria, Francis Joseph, was lawfully crowned King of Hungary, which was once more assured entire control of its internal affairs.

**The Ministry of Public Instruction**—The political idealism which marked the deliberations of the Hungarian leaders in the short term of independence achieved in 1848 found new and permanent expression in the measures adopted for the internal conduct of the state in 1867. Baron Eotvos was again made Minister of Worship and Public Instruction, and a central department of education was constituted which by its scope and divisions illustrates the completeness of the service under its direction. The ministry is organized in ten departments, including distinct departments of higher, secondary, and elementary education, practically five departments are subdivisions of the last named. The staff of the ministry includes a corps of inspectors and several educational experts. The Hungarian Board or Council of Education formed by the appointment of the King or the minister is primarily an advisory council to the minister, but it also has important executive functions. The laws pertaining to education are prepared and enforced by the minister who has exclusive jurisdiction over schools maintained by the State. The right of inspection is also exercised over other schools so far as consistent with their legal autonomy and in proportion to the measure of state assistance which they receive.

**Elementary Education.**—In his capacity as Minister of Public Instruction Baron Eötvös, in 1868, one year before the adoption of a new education law by Austria, drew up and carried through the legislature the law of elementary education in Hungary (Act XXXVIII, 1868),

making the education of all children compulsory, in day schools from the ages six to twelve; in continuation schools (Sunday or evening) from twelve to fifteen. The civil officers of the parish were required to compel the enforcement of the compulsory provisions. Children educated privately were required to pass an annual examination at the elementary public school. The duty of establishing and maintaining schools was imposed upon the parish authorities, but denominational schools were recognized. It was further ordered that where the local authorities and the religious denominations should both fail to make due provision of elementary schools, the Minister of Public Instruction, acting in the name of the State, should provide schools. As a consequence of the legal provisions the elementary school system comprises national schools, public schools managed by the civil parish (cities, villages, etc.), denominational schools adopted as public schools, and schools under private managers. A measure of unity is secured by legal conditions binding upon all public schools. These conditions comprise a common program and specified requirements as to school buildings and classrooms; they make eighty the limit of the number of pupils in a school; they require that boys and girls shall be taught separately and that the schools shall be open for at least eight months a year in the country and nine months in the city. Teachers must possess the legal qualifications, must receive, at least, a certain minimum salary, and must be guaranteed a pension after the prescribed period of service. Finally the law requires local inspection of schools by duly qualified officials. These provisions appear the more remarkable when it is remembered that the Hungarian school law preceded by thirteen years the first of the series of laws regulating the present system of primary education in France, and by two years the passage of the act of 1870 by which the English government assumed direct responsibility for the education of the masses. In its regard for established customs and vested interests, the Hungarian law recalls the salient provisions of the English Act, which was undoubtedly inspired in part by the interchange of counsels between its author, Mr W. E. Forster (*q.v.*), and his celebrated contemporary, Baron Eotvos.

The law of 1868 prescribed somewhat minutely the internal organization of the schools. It distinguished two courses of elementary education: the six years day school course and the three years continuation course, and required that state schools and communal schools should make provision for both. The six years school may be under the management of one or more teachers, and the schools are called undivided or divided (graded) accordingly. Although the law required separate schools for boys and girls as a matter of theory, mixed schools are very common. The obligatory

program for every school includes, besides the three elementary branches, religion and ethics, grammar, geography, natural history, natural science, civic rights and duties, history of the constitution, elements of geometry, drawing, singing, physical exercises, needlework for both boys and girls, and practical training in agriculture and gardening. An official syllabus is issued by the Minister from time to time, dealing with the purposes and matter of the several subjects and giving extended and admirable suggestions to teachers for the work of instruction. A section of the syllabus is devoted to the undivided schools, which present special difficulties. The national language and literature (Hungarian or Magyar), the national history and the rights and duties of citizens form the very core of the school instruction; hence the intense sentiment of national life diffused throughout the land. Second only to this group of studies is the instruction in natural science, with its complement in the training in agriculture. The latter, which begins in the fifth school year, is thoroughly systematized and pursued with enthusiasm as an essential factor in national prosperity. The branches of elementary instruction are reviewed in the continuation schools with some extension and with greater regard to their ethical and social bearings. By the official syllabus of 1902, the continuation course in agriculture was brought into closer relation with the immediate local conditions, and, as a result, the technical side of the continuation schools has been highly developed in parts of the country. The greater number of these schools have farms or gardens attached, forty-five schools of this class have large experimental farms and are provided with special teachers of agriculture.

The judicious spirit which marks the law of 1868 is illustrated by the special provision for communities below and above the general level of the country. The parish authorities were charged to provide for the instruction of children living on farms within their jurisdiction, either by means of schools or itinerant teachers. This is a matter of peculiar significance, since in the great Lowland (Alfold), which constitutes a third of the entire territory of the realm, the greater part of the inhabitants live on widely scattered farms and are unable to comply with the school law; hence the State has intervened and is supplying the means of elementary education to these scattered homesteads. In other parts of the country, especially in the northwest and southeast districts, the multiplicity of languages and of church affiliations threatens the unity of elementary education. Here again the State intervenes, and without interfering with parochial or other schools, establishes state schools.

The organization of city schools differs from that of rural schools not alone through force of circumstances, but by direct enactments

## HUNGARY

These provide for city high schools based upon the fourth year of the elementary school course and continuing the instruction of pupils on quite different lines. The city schools for boys, which are practically the same as the burgher schools of Austria, are organized in four classes (originally in six), and their studies are the same as those of the four junior classes, or forms, of the secondary schools. The crowded obligatory program includes religion and ethics, the mother tongue of the pupils, style, and history of literature, the Hungarian language, the German language, arithmetic, including practical arithmetic, geometry, the geography of Hungary, and universal geography, history, natural history, physics, chemistry (the last three with special regard to industry, commerce, and agriculture), rural economy and industry (in accordance with the wants of the parish and the surrounding country), outlines of common and civil law, bookkeeping, drawing and calligraphy, singing, gymnastics and drill (*Regulations* 1879). Recently sloyd was introduced. Optional branches are Latin, French and other languages, and music. The city schools for girls included four years or forms from the start. Pupils who complete the course are admitted to the schools of industry and commerce for girls, or, if they pass examination, to the fifth class of girls' high schools, if fourteen years old, they are eligible for admission to normal schools (*Regulations* 1887).

**Teachers** — The training of teachers was a cardinal principle in the scheme of national education comprised in the law of 1868. Normal schools existed in Hungary before this date, but the law made explicit provision for their classification, distinguishing between normal schools for the preparation of teachers of elementary schools and those for teachers of higher schools, and fixing the standards of graduation, conditions of students' life, etc. All the authorities entitled to establish elementary schools may maintain normal schools, but they must conform to the legal requirements. Official regulations of 1903 introduced uniformity for all normal schools of the same order, state and private. The program of the elementary normal schools is arranged for four years, and comprises general subjects and those strictly professional, the latter being enforced by the critical observation of the work of student teachers in the model or practice schools. The Hungarian language and literature, Hungarian history, and the German language are obligatory subjects in the course, other languages spoken in Hungary are optional. In the normal schools for women, which follow the same general program as those for men, special attention is given to domestic economy, household work, artistic embroidery and needlework, dairy work, care of poultry, etc., and the official instructions emphasize the importance of these industries, and of women's

## HUNGARY

influence as exerted through the home life. The recent movement for the higher education of women promises also to open up other channels for the exercise of their artistic and manual skill.

Above the ordinary normal schools are two state colleges which prepare teachers for the higher elementary and city schools, and serve as models for similar colleges maintained privately. The course of instruction covers three years, and is conducted on the group or department system. The central groups are (1) languages and history, (2) mathematics and natural science. The subjects comprised in each are arranged in special or sub-groups, all additional branches form side groups. By reason of this arrangement students may enter for special subjects and at any time. In all sub-groups the following subjects are obligatory: (1) preliminary study of philosophy (psychology and logic), (2) theory of education and teaching, with history of educational theories and institutions, (3) history of Hungarian literature, (4) teaching in the practice schools. One of the side groups comprises music, vocal and instrumental, which is included in the course of instruction in all training colleges. In school programs generally, Hungarian music is second only in importance to the Hungarian language and literature.

Tuition is free in all state normal schools, and the expenses of boarding are covered partially or entirely by scholarships. Intending teachers, whether graduates of normal colleges or others, must pass examination for a teacher's diploma, conducted by a government board composed of members of a training college staff and representatives of the ministry. Separate boards are constituted for the examinations for the different grades of diplomas. Every diploma must certify that the recipient knows the Hungarian (Magyar) language, a requirement which was extended to teachers of denominational schools by a law of 1907. In all continuation schools the Hungarian language has been made the medium of instruction.

**Conditions of Service** — Teachers of state schools are appointed by the Minister of Public Instruction, of communal public schools by local boards, of denominational schools by the managers of the same. The teacher of a public school has a life tenure unless removed for crimes or misdemeanors, and in accordance with recent laws a teacher must receive a specified minimum salary, whether engaged in a public or private school (Acts XXVI and XXVII, 1907). A pension fund is maintained partly by state and local appropriations, and partly by assessments on the individual salaries, and teachers can claim a pension after ten years' service, after forty years' service they receive full pension (Acts of 1872, 1891). From the same fund aid is extended to the widows and orphans of teachers. The solic-

lude for the welfare of teachers has led to the creation of "Teachers' Homes," where the children of teachers and school officers are cared for while pursuing professional study. The Teachers' Home in Budapest, the Francis Joseph Home, was opened in 1899. The Hunyadi Teachers' Home at Kolossvár began operations in September, 1904. Both the intellectual and social welfare of teachers are promoted by their membership in teachers' guilds, which is required by the law of 1868. These guilds, or associations, are animated centers of pedagogical discussion and reform as well as mutual benefit societies. Teachers have the advantages of the *Hungarian Museum of Educational Appliances* at Budapest, which was opened in 1877 and in 1906 combined with the Teachers' Library. The annual appropriation for the entire institution is about 12,000 crowns (\$2400).

**Unifying Influences** — In the union of public and denominational schools, the Hungarian system of elementary education resembles that of England. But whereas the sense of national solidarity is preserved in England by many influences stronger than the school, in Hungary the school is the very source of its existence. Hence, of necessity, the Hungarian language is required in all schools, elementary and normal, since unity of language is essential to national consciousness. Moreover, so far as possible, the law seeks to impart a common character to all public schools of the same order, whether established by the State or the commune, and to this end has made very careful provision for their supervision and inspection. State schools are under the control of boards of trustees formed partly by election and partly by appointment. Parish schools (municipal and district) are under local school boards whose members are appointed by the local administrative councils. These school boards attend to the external affairs of the schools, including the appointment of teachers, their salaries, etc. The professional supervision and inspection of public schools is intrusted to the royal inspectors and the local administrative councils. The inspectors are appointed by the King upon the nomination of the Minister, one for each county or school area. They are the responsible heads of the system, exercising practically the same authority as a state superintendent in the United States; they are also the intermediaries between the local authorities and the ministry. The chief inspector is assisted by a corps of sub-inspectors.

The duties of the local council in respect to school affairs are judicial and executive (Act XXVII, 1876, amending provisions of the act of 1868). Although the managers of denominational and other private schools have independent control of their institutions, they are subject in a measure to the supervision of the royal inspector and to the local councils.

**Statistics of Elementary Schools** — According to the official report, for the year 1907, the total number of children in Hungary of the obligatory school age was 3,125,000 (1,564,000 boys, 1,561,000 girls). The enrollment in elementary schools was 1,848,176 children (948,918 boys, 899,258 girls); in general continuation schools 347,000; in the agricultural continuation schools 140,655; and in the higher schools of this class 8356, or a total enrollment in continuation schools of 496,011. This gives a grand total of 2,344,187, or 74 per cent of the children of obligatory school ages. The corresponding total for 1909 was 2,775,278. The number of elementary schools in 1907 was 16,561, classified as follows: State schools, 2046; district, 1473; denominational, 12,734; private, 271, proprietary, 37; of the total number of schools 68.5 per cent were "undivided" schools with one teacher each. The number of teachers engaged in public elementary schools was 30,194, of whom 28,600, or 94 per cent, had government diplomas. Of the elementary schools 11,527 had a general, 2040 an agricultural, 102 a general and an agricultural continuation school attached. 57.67 per cent of the said schools used Hungarian (Magyar) as the exclusive language of instruction; while in 17.97 per cent other languages of instruction were used in addition to Hungarian. Consequently the percentage of schools where Hungarian is the language of instruction may be put at 70.91 per cent. In 1907 the amount appropriated for state elementary schools was 10,570,010 crowns (\$2,114,002); the amount appropriated for the subvention of public parochial, denominational, and private schools was 4,864,000 crowns (\$972,800), or nearly half the sum appropriated for schools supported entirely by the State.

**Supplementary Agencies** — *Infant Homes.* — The system of infant protection for which Hungary is noted may be said to date from the efforts of the Countess Teresa Brunswick, who, with the support of Count Széchenyi, the leader of the reform movement in Hungary in the early years of the nineteenth century, established the first infant home at Buda, in 1828, called *Garden of Angels* (*Angyalkert*). In 1836 an association was formed for carrying on the work, in which several prominent men, among them Louis Kossuth, were actively engaged. Through the efforts of this association a training college was established for directresses of infant homes. In 1848, when the War of Independence broke out, eighty-nine homes were in operation, all of which were greatly crippled by the war. Baron Eotvos proposed to include this work in the measures of 1868 pertaining to popular education; but, owing to the objection of the legislature, the matter was deferred for some years. Meanwhile the first Froebel kindergarten was opened (1869) and an association formed to promote this work. This association and the *Hungarian Infant*

*Protective Association* are still active centers of efforts in behalf of young children. The first legislative provision concerning this matter deals with the qualifications of teachers of infant schools (Act XXXII, 1875). The complete organization of the system of infant protection was accomplished by the law of 1891 (Act XV). The special features of the system are: provision for the establishment of infant homes by the State and by local authorities; the requirement of special training for the teachers and of other persons on the staff of the homes; the obligation placed upon parents to send their children between the ages of three and six, who cannot be properly cared for at home, to infant homes, under penalty of a fine ranging from twenty fillér to one crown. The magnitude of this work is indicated by the following statistics: number of infant homes reported in 1906-1907 (a) state, 582, (b) municipal, 1421; (c) denominational, 338; (d) others, 254, total, 2595, among these are 1913 which make use of the Hungarian language only. In these homes were 245,214 children, of whom 57 per cent were Hungarian-speaking, there were 1913 certified mistresses, 427 certified nurses and 332 uncertified nurses, total staff, 2672, the expense of maintenance was, in round numbers, 3,000,000 crowns (\$600,000).

Among the marked features of infant homes should be noted the admirably planned and equipped buildings. They are provided with ample halls, playgrounds, and covered courts, where the children engage in free sport and directed games. The system of training is remarkable for its sympathetic adaptation to the impulses and capacity of childhood, the awakening of the national spirit by songs, stories, and pictures of national life, for the use of the Hungarian language, and for the grasp of Froebelian principles, with modifications to suit the national circumstances and purposes.

*Defective Children* — The provision for the care and training of the blind, the deaf and dumb, and of children who are mentally and physically defective, has been brought under the supervision of the State, in the same manner as the system of popular education. The following statistics relate merely to the educational side of this work, as reported in 1907.

INSTITUTIONS	NUMBER OF CHILDREN	FUNDED CAPITAL, CROWNS
Day homes . . . . .	1652	1,900,614
Orphan asylums . . . . .	4314	17,512,007
Children's Aid societies . . . . .	4339	660,989
Summer colonies, etc . . . . .	1032	230,000
Institutes for the Deaf and Dumb (3) . . . . .	91	1,212,368
Institutes for the Blind . . . . .	88	131,000
Homes for child cripples . . . . .	64	131,000
Home for feeble-minded children (1) . . . . .	105	32,529

**Industrial and Commercial Education** — Industrial education has a long history in Hungary, beginning, as in other countries, with schools established by certain religious orders, and gradually coming under the supervision and fostering aid of the State. Commercial education has a briefer history, and although regulated by special laws was left largely to the initiative of societies and private managers until the close of the last decade. The significant facts in the progress of this practical education since 1867 are the measures adopted for their regulation by the State.

The agencies for both industrial and commercial training fall into two general classes, apprentice schools and technical or professional schools proper. The apprentice schools are under the direction of the Minister of Public Instruction; trade schools or industrial technical schools, and also the technical high schools, pertain directly to the Ministry of Commerce, although the education department is consulted in respect to their scholastic interests. Commercial education is organized under the direction of the Minister of Public Instruction, but in regard to the higher order of commercial institutions the departments of education and of commerce act conjointly. The courses of training for apprentice schools are based upon those of the elementary primary schools; the industrial and commercial secondary or high schools, in like manner, rest upon the more advanced courses of the higher primary and city schools. Hence these forms of specialized training bear the same relation to the education of the artisan and trading classes as the agricultural schools bear to that of the farming population. In accordance with the purpose of maintaining vital relations between technical schools and the industries to which they pertain, the organized agricultural schools are placed under the Ministry of Agriculture.

*Apprentice Schools* — The establishment of apprentice schools is obligatory upon all communities in which there are fifty apprentices working in shops or factories, the masters of trade are also obliged by law to procure the attendance of their apprentices at these schools (Laws of 1872, 1884, 1893). Boys may enter the apprentice schools at twelve years of age after finishing the course of the elementary school. The instruction given in the evening and on holidays occupies seven hours a week, two hours on each of two week days, and three hours on Sundays; the latter are exclusively devoted to drawing. The branches of instruction are (1) the mother tongue, (2) geography, history, and nature study, (3) penmanship, (4) arithmetic and bookkeeping, (5) drawing and sketching. The course is given in detail by the central government. If the religious communities desire to have these apprentices taught religion, they may do so, but they must do it at their own expense. In 1906-1907

Hungary had 465 apprentice (evening and holiday) schools with 83,518 pupils and 3607 teachers; of the entire number of schools fifteen were state schools, 423 district schools, two denominational, and twenty-five belonged to factories and companies. The expenditure for these schools was provided as follows: 437,886 crowns were allotted by the Treasury and from the National Apprentice Fund; 1,241,758 crowns contributed by district authorities and other supporters, thus the total necessary expenses amounted to 1,679,644 crowns (\$335,928). In the same year there were ninety-one commercial apprentice schools, of which two were state schools (Fiume and Brasso), sixty-three district, and twenty-six belonging to companies. The total number of pupils was 7160, and the number of teachers, 417. The sum disbursed by parish authorities and companies for the schools was 223,983 crowns.

The commercial courses for women in 1906-1907 numbered twenty-four, of which seven were in Budapest. The pupils numbered 1456, and the expense of the courses, amounting to 141,452 crowns, was met chiefly by tuition fees.

The system of technical schools is crowned by the Polytechnicum at Budapest, and the system of commercial education by four institutions of high standing, namely, the Oriental Commercial Academy, Budapest, a training college for teachers of commercial schools, and two commercial academies, one at Budapest, the other at Kolozsvár. The total expenditures of the Education Department upon trade and commercial instruction in 1907 was 1,450,638 crowns (\$290,127).

**Secondary Education** — In his project for the reform of education in Hungary Baron Eotvos included the secondary schools, but the time was not favorable for any material change in institutions so deeply rooted in custom and sentiment, and it was not until 1883 that a measure was carried dealing with the system of secondary education. Previous to this time its development had followed the same course in Hungary as in Austria, excepting only for the authorized independence of the schools of the Reformed and Eastern churches, which was exercised mainly in respect to administration and to religious instruction. Many influences, social and professional, conduced to the general adoption of the courses and standards of instruction prescribed by the regulations of 1777 and 1806 (*Ratio educationis*). These regulations prevailed till 1849, when, under the régime of absolutism, the Austrian system was forced upon the public secondary schools of Hungary. The endeavor, during this period, to make German the medium of instruction was partly counteracted in Hungary by the general use of Latin, which accounts for the command of Latin as a spoken language, on the part of educated Hungarians even to the present time. A permanent advantage from the alien influ-

ence was the official recognition of modern studies, which was continued after Hungary recovered its autonomy.

The present organization of secondary schools is based upon the law of 1883, the work of August Trefort, Minister of Public Instruction from 1872 to 1888. This law recognizes secondary schools of two orders: classical, represented by the gymnasia, modern, represented by the realschulen. The programs of the two are nearly identical in duration (eight years) and study scheme, with those of the corresponding schools in Austria (*qv*). A single difference should be emphasized, namely, the inclusion of both the Hungarian and German languages as compulsory subjects, and the conduct of the final or leaving examination in the Hungarian, requirements applied equally to state and denominational schools. The widespread complaint of the overcrowded programs of the secondary schools led to a revision of the same in 1890 under the direction of Dr. Julius Wlassics, at that time Minister of Public Instruction. Among the changes effected was that of allowing students in the classical schools a choice between Greek and certain specified studies, as a consequence Greek has been dropped in many gymnasia. Notwithstanding this change, the literary requirements are still excessive.

As to the relative standing of the gymnasia and the realschulen, it should be observed that students who pass the final examination of the classical schools may be admitted to any university courses, students from the realschulen are restricted as regards rights of entrance to the polytechnic, the mining, forestry, and agricultural high schools, and to university courses in mathematics and natural science.

The professors of secondary schools must be university graduates who have supplemented their general studies by professional training, and must have successfully passed the government examinations for admission to the service. A seminary and practice school were established at Budapest in 1872, in connection with the university faculty of arts, by Dr. Kármán, who had been a student in Ziller's Seminary at Leipzig, and was thoroughly imbued with the Herbartian spirit. In 1895 a state normal college for secondary teachers was organized at Budapest under the auspices of Minister Wlassics, and this, also, is a center of Herbartian principles. Teachers of secondary schools attain to full appointment after three years' probationary service. At this stage they receive an annual salary of 2000 crowns (\$400) in the capital, and 1600 crowns (\$320) in the provinces. The teachers under full appointment are divided into two classes. Salaries in the lower class begin at 2600 crowns and rise by periodical increase to 3200 crowns; in the higher classes the salaries increase by successive additions, from 3600 to 4400 crowns. Directors receive from 4800 to 6000

## HUNGARY

**crowns** After thirty years' service teachers and directors may be retired with a pension.

**Statistics** — The total number of secondary schools reported in 1906 was 202, of which 170 were classical and thirty-two modern. Of the classical schools thirty-eight were maintained by the State, and of the modern schools twenty-five. The number of secondary students was 68,159, of whom 50,283 were of the Hungarian nationality and 6254 Germans. As regards religious affiliations, the largest contingent, *i.e.* 27,499, were Roman Catholics, and the next largest 14,455, of the Jewish faith. The total number of teachers was 3711. The expenditure for secondary schools in 1906 amounted to 19,347,745 crowns (\$3,869,549). Of this amount 3,380,587 crowns (\$676,116) were derived from fees, the remainder from public appropriations and endowments. The estimated value of the property of secondary schools is about 90,000,000 crowns (\$18,000,000).

**High Schools for Girls** — Separate schools and a distinctive type of education for girls mark the Hungarian system. This is illustrated by the arrangement of city schools and by the creation of special high schools for girls. The first of the high schools was established at Budapest in 1875, and the example was soon followed by municipal and church authorities. The course of instruction was based upon the sixth year of the elementary school, and arranged for six additional years. The purpose to maintain high scholastic standards in the new schools was indicated by requiring the same qualifications for the teachers as are required for those of secondary schools for boys. The present organization of the high schools was determined by a ministerial decree of June 12, 1901. The official program comprises the following studies: religion, Hungarian grammar and literature, German, French, psychology and theory of education, history, geography, zoology and botany, mineralogy and chemistry, hygiene, housecraft, physics, arithmetic, drawing, calligraphy, needlework, singing (optional from the fifth class upward), physical exercises. Among the optional subjects are the English and Italian languages, taught from the fourth class upwards in two hours a week respectively.

In the year 1895, by the authorization of Dr. Julius Wlassics, young women were admitted to the university, and thus were enabled to devote themselves to philosophical, medical and pharmaceutical callings, with certain restrictions. It was therefore necessary to make arrangements for a course of studies preparing them for the new privileges. For this purpose a course of studies on classical school lines was established at the Budapest High School for Girls during the school year 1897-1898; so that those who were preparing for the university might have special and suitable training, commencing with the fifth

## HUNGARY

class and lasting four years. The Budapest High School has since been transformed into a girls' classical school, and other schools of the same character have been established. Hence the education of girls is now proceeding in two courses: one marked by the predominance of modern languages and domestic science; the other closely assimilated to the classical school for boys. The high schools for girls have mixed faculties of men and women, and their development has created a demand for women teachers having the same qualifications as the professors of secondary schools for boys, receiving the same salaries, and enjoying the same distinction. In 1905-1906 the high schools for girls numbered thirty-two, of which sixteen were state schools. The number of students was 5817, including 1008 boarders. The majority, *i.e.* 5367, were Hungarians. The schools employed 524 teachers, of whom 343 were women. The expenditure for the high schools for girls in 1905-1906 was, in round numbers, 1,970,000 crowns. In the budget of 1907 the State appropriated for this purpose the sum of 1,325,000 crowns (\$265,000).

**Higher Education** — The Royal Hungarian University of Sciences of Budapest is the chief center of classical and scientific study and research in the kingdom. Its origin is traced to the establishment of a university under the direction of the Jesuits at Nagyszombat in the seventeenth century, it was nationalized in the eighteenth century and transferred from its original home to Budapest. The university of Kolozsvár (Klausenburg) was founded in 1872 by the incorporation of the existing Academy of Law and Institute of Surgery. The Royal Polytechnicum was organized as a university of technical sciences in 1871. The latest official statistics pertaining to these three institutions are presented in the following table —

State Universities	Dates of origin and date organization	Total students 1911	Professors and assistants	EXPENDITURES		Vols. in Library
				Crowns	United States equivalents	
Budapest	1635 1783	6858	351	3,746,859	\$760,612	482,000
Kolozsvár (Klausenburg)	1581 1872	2359	136	1,764,011	358,094	116,090 <sup>1</sup>
University of Technical Sciences (Budapest)	1782 1871	1349	155	1,430,846	349,841	90,395

<sup>1</sup> Not including the vols. belonging to the library of the Transylvanian National Museum, with which it is united.

The distribution of university students by faculties and the number of doctors' diplomas conferred in the year of the latest available report, were as follows:—

## HUNGARY

FACULTIES	BUDAPEST			KOLOZSVÁR		
	Number of students		Number of diplomas	Number of students		Number of diplomas
	Ordinary	Extraordinary		Ordinary	Extraordinary	
Theology	78	9	6			
Law	3091	152	309	1428		211
Medicine	1258	166	149	202	82	20
Arts	1203	234	74	360	59	18

In the same year the distribution of students by faculties in the technical university and the number of diplomas conferred were as follows in the department of engineering, number of students, 382; number of diplomas conferred, 106, department of mechanical engineering, students, 587; diplomas, 121; architecture, students, 96; diplomas, 13; general department, students, 8; diplomas, 11.

Among recent events in the history of the University of Budapest, which illustrate both the scope of that institution and the general development of higher education, the following are particularly noteworthy. The expansion of the faculty of law to include political science and the institution of seminars for the promotion of research and practical training. In the medical faculty special courses of training for pharmacists and school doctors have been established. In 1889 the Pasteur Institute and Hospital was established. The faculty of arts from its foundation served as a preparatory course for students of the other faculties, and it has become also a center of training for teachers of secondary schools and an examination board for candidates aspiring to that service. Since 1885 the faculty of arts has comprised seminars which are partly for the training of teachers, partly for the purpose of initiating students into the methods of research. The faculty can boast of five seminars, those of classics, modern philology, history, geography, and mathematics. By a royal decree of Nov. 18, 1895, women were admitted as undergraduates of universities and university colleges in order that they might be prepared as teachers, doctors, and chemists. Permission is given to women students in each case after a statement has been made by the university or college in question and diplomas are issued to them after a successful completion of the prescribed university career. In addition to these two universities, the Minister of Education announced (1912) a bill to provide for the establishment of two new universities at Pressburg and Debreczin, only the former to include a medical school. A royal academy has existed at Pressburg since 1794, with a faculty of law and political science and courses in philosophy. At Debreczin a Reformed Higher Institution

## HUNGARY

(*Hochschule*) was established in 1549 and now has theological, legal, and philosophical faculties with 277 students in 1910.

The Baron Joseph Eotvos College is a unique institution at Budapest, the object of which is to give deserving students of the Budapest University, who intend to enter the teaching profession, an opportunity for holding social intercourse with their fellows and of acquiring the necessary theoretical and practical knowledge to qualify them for their work. The college is directly subordinate to the Minister of Public Instruction, who delegates his authority to the curator. For the expert guidance of the resident students four tutors (chosen by the curator from among the teachers in the service of the State) are appointed by the Minister (for periods of three years in rotation) for special duties. They are present in the college during the hours devoted to private study, to give individual or combined instruction to the candidates, and, as occasion arises, to hold special courses of lectures.

Higher education in Hungary includes, further, independent colleges of theology maintained by the various religious denominations; and colleges of law. The schools of midwifery were raised to the rank of state professional schools by regulations of 1873, and placed under the control of the Minister of Public Instruction. The Royal Hungarian College of Mining and Forestry, under the direction of the Minister of Finance and the Minister of Agriculture, makes provision for the scientific education of surveyors of mines, surveyors of smelting works, and surveyors of forestry. It was attended in 1907 by 355 students, 117 in the mining department, 238 in the forestry department. Students are admitted by competitive examination, and those who fail to satisfy the rigid requirements for promotion during the four years' course are eliminated. Tuition is free; the purpose of the school is to secure a body of highly trained experts for the state service of mining and forestry. In addition to the liberal support of higher education, the State contributes to the maintenance of the schools of painting and sculpture and the conservatories of music, which preserve from age to age the distinctive traits of national art. The following art institutions are under the immediate direction of the Minister of Public Instruction, and receive liberal appropriations annually from the State. The Royal Hungarian College of Art is both a school for the training of teachers of drawing and for the development of independent artists; the students for 1907 numbered 347, of whom ninety were women; the State grant for the year was 183,080 crowns (\$36,616). A special school of painting for women was established in 1885 under the auspices of the ministry. The annual appropriation for the school is about 21,000 crowns (= \$4200). The National Academy of Music is entirely supported by

the State at an annual expenditure of about 230,000 crowns (\$46,000). The Theatrical School was opened in 1863 in connection with the National Theater, and in 1873 was put under the charge of the Minister of Public Instruction. The age for admission to the school is sixteen for women and eighteen for men, and only such pupils are retained as show decided dramatic talent. The diploma of the school admits the recipient to membership in the National Association of Actors. In 1907 the State appropriated 82,000 crowns (\$16,400) for the current expenses of the institution. A. T. S.

**HURON COLLEGE, HURON, S D** —

A coeducational institution established by the Presbyterian Synod in 1883 at Pierre as Pierre University; the title and location were changed in 1898. Academic, collegiate, commercial, music, and elocution departments are maintained. The entrance requirements are equivalent to sixteen points of high school work. The degrees of A B and B S are granted on the completion of appropriate courses. The faculty consists of twenty-four members.

**HUTCHESON EDUCATIONAL TRUST, GLASGOW, SCOTLAND** —

An endowment left by George Hutcheson (1550-1639) and Thomas Hutcheson (1589-1641), public writers and notaries of Glasgow, and now devoted largely to educational purposes. George Hutcheson left a tenement of land for the building of "one perfyte hospital for entertainment of the poor, aged, decrepit men to be maintained therein," and for its maintenance added bonds of the value of about \$12,000. Thomas Hutcheson supplemented this by a sum equal to about £600, and for himself gave bonds amounting to about £12,000 for founding in connection with the hospital "a commodious and distinct house of itself for educating and harboring twelve male children, indigent orphans, or others of the like condition and quality, sons of burgesses." In 1821 a Royal Charter was obtained. The scope and purpose of the endowment was extended, as in the case of many similar endowments in Scotland, for educational purposes. In 1876 the school was extended and a new school was added for girls, both schools being called Hutchesons' Grammar School. Moderate fees are charged and a limited number of free foundationers are admitted.

**HUTCHINS, JOSEPH** (1747-1833) — Text-book author and college professor, was graduated from the University of Pennsylvania in 1765, and was for many years professor in Franklin College. His *First Principles of English Grammar* (1790) antedated the text-book by Lindley Murray (q v) by five years.

W. S. M.

**HUTTEN, ULRICH VON** (1488-1523). — German humanist and reformer. Of an cr-

ratic and unstable character, living generally on the generosity of patrons of learning, Ulrich von Hutten won the admiration and friendship of many of the humanists whose center was at Erfurt. Hutten's chief works were the *De Arte Versificandi, Liber unus* (1510), which gives the rules of Latin prosody in 422 hexameters; patriotic poems addressed to Emperor Maximilian, who gave him the laureate crown in 1517; orations against Ulrich, duke of Wurtemberg, who had murdered a relative of Hutten, and in the last stage of his career, when he joined the cause of the Reformation, prose writings and poems in the vernacular, in which he was as successful as with Latin. Hutten is credited with an important part in the publication of the *Epistolæ Virorum Obscurorum* (q.v.). It is now well established that in the first part of the letters Hutten had no share whatever, but he was probably the chief author of the second part which appeared in 1517. A man of strong impulses and considerable ability, Ulrich von Hutten threw himself as enthusiastically into the fight for liberal culture as into the cause of political and religious freedom.

**HUXLEY, THOMAS HENRY** (1825–1895).

—Scientist, educational thinker, and social reformer, was born at Ealing, near London, May 4, 1825, the son of a secondary schoolmaster. Briefly educated at Dr Nicholas's school in Ealing, where his father was a teacher till 1835, Huxley showed an early turn for metaphysics and for scientific inquiry. The lad's real education came through private reading, conversation, and intimacy with older people. Anatomical studies and Carlyle's writings on philosophy and history deeply influenced Huxley during adolescence. Admiration for Carlyle impelled him to acquire a knowledge of the German language subsequently invaluable to him as a scientific thinker. In 1841 he went, a boy of seventeen, as assistant to a medical man, Mr Chandler, in Rotherhithe. Among the population surrounding the London docks, he came face to face with the grimmest aspect of the social problem, and throughout life was a zealous reformer of social conditions, holding firmly to the middle way between repressive collectivism and crippling *laissez-faire*. Studies at Charing Cross Hospital (especially under Wharton Jones) completed his medical training, during which he won brilliant distinction at the London University. In 1846 he was appointed assistant surgeon to H.M.S.

*Rattlesnake*, a frigate sent out by the British Admiralty on an exploring expedition to New Guinea. Thus Huxley, like his intimate friends, Charles Darwin (q.v.) and Joseph Dalton Hooker, began his scientific career on board a ship of the British Navy. His work on the *Rattlesnake* established Huxley's scientific position. On his return to London in 1851 (aged twenty-six) he was elected Fellow of the Royal Society, becoming a member of its Council and receiving its Royal Medal in 1852. But pure science was long in bringing Huxley pecuniary preferment. In 1852 he, like his friend Tyndall (q.v.), was an unsuccessful candidate for a professorship at the University of Toronto. The death of his mother, and his father's illness, in 1852, combined with his own failure to find a suitable post, brought him nearly to despair. He was on the brink of giving up science and of emigrating to Sydney as doctor or squatter. In 1854 the tide turned. He was appointed lecturer in the Government School of Mines in Jermyn Street, London, and entrusted with coast survey investigations under the Geological Survey, to which he became naturalist in 1855. He also was appointed lecturer on comparative anatomy at St. Thomas' Hospital. Now established, he rapidly rose to eminence in the scientific world.

A characteristic of Huxley's writing was his intimacy with the best current scientific thought in France and Germany. No earlier English scientific writer had shown the same European knowledge. Huxley was one of the few who were initiated by Darwin into the argument of the *Origin of Species* before the publication of the book, which was submitted to the judgment of Huxley, Lyell, and Hooker. In Darwin's words, he acted as the latter's "general agent." His famous reply to Bishop Wilberforce at the Oxford Meeting of the British Association in 1860 gave him national fame. In 1862 Huxley began his scientific lectures to working men. No one did so much to secure public acceptance for the thesis of natural selection.

Huxley as a teacher was magnetic. His students found his intense love for science infectious and his lectures memorable. As Dean of the Royal College of Science, London, he introduced changes of organization which are of historical importance from the point of view of educational method.

Huxley showed an untiring interest in questions of education. In 1854 he delivered at St. Martin's Hall, London, an address on the *Educational Value of the Natural History Sciences*, urging that biology demands a prominent place in any worthy scheme of education. In 1865 he supported the scheme for a group of international colleges (to be established in England, France, and Germany, so that a boy could in turn acquire a sound knowledge of all three languages while continuing the same course of education), which had been put for-

ward by Dr Leonhard Schmitz and Richard Cobden, but was fatally interrupted by the Franco-German war of 1870. At the same period he supported Dean Farrar's (*qv*) proposals for the introduction of scientific teaching into the great Public Schools. In 1866 he published *Lessons on Elementary Physiology*, a textbook which had great formative influence upon later educational manuals. In 1868 he addressed the South London Working Men's Club on *A Liberal Education and Where to Find It*.

In 1870 Huxley published the *Lay Sermons*, a model of style in the accurate popularization of scientific thought. In the same year (the Elementary Education Act having just been passed) he wrote a powerful essay on *The School Boards, What They Can Do and What They May Do*. He was elected a member of the first London School Board, and had an almost determinative influence both in planning the course of study and in the retention of the Bible in the curriculum. He advocated infant schools, continuation schools, technical education, and "an educational ladder from the gutter to the University." The first elements of physical science were to be taught in the schools. "There is no form of knowledge or instruction in which children take a greater interest." Girls were to be taught the elements of household work and of domestic economy. Physical training and drill were to be part of the regular business of every school. Drawing and music, as civilizing arts, were also to find a place in every course of training. History, except the most elementary notions of it, he regarded as too advanced for children of elementary school age. He declared himself "in favor of reading the Bible, with such grammatical, geographical, and historical explanations by a lay teacher as may be needful, with rigid exclusion of any further theological teaching than that contained in the Bible itself." But Huxley was strongly opposed to any teaching of religious formularies, *eg* even the doctrine of the Trinity, in elementary schools aided from public funds.

Huxley became secretary of the Royal Society in 1871 and president in 1880. In 1881 he declined the Linacre Professorship of Physiology at Oxford and to be nominated for the mastership of University College, Oxford. He refused all titular honors from the State, except a Privy Councilorship in 1892. The latter he accepted because, though incidentally carrying a title, "it was an office, in virtue of which a man of science might, in theory at least, be called upon to act as responsible adviser to the Government should occasion arise." His connection with the Science and Art Department from 1854 to 1890 was intimate and loyal. Of the good which that department did in stimulating scientific study and teaching he was one of the chief authors. But he was not blind to the defects of the system, payment by results,

which he accepted as the best practicable plan. From 1877 onwards, Huxley was an ardent and powerful advocate of technical education. The great address given at Manchester in 1887 is a *locus classicus* of contemporary English thought on the subject.

But he was out of sympathy with modern developments of English thought as to the relation between the State and secondary education, holding that, while social welfare justifies a system of compulsory elementary education with a rich curriculum, beyond that individuals must be left to rise through innate capacity, rather than be lifted by state help into places for which they may have no real qualification.

Since Thomas Arnold, Huxley was perhaps the most powerful personality in English education. Brave as a paladin, absolutely fearless and disinterested, profoundly learned, affectionate, humorous, tender, artistic, at heart intensely religious, but the implacable foe of dogmas in which he did not believe and of ecclesiastical authority which he distrusted or denied, he represented at its best a transitional phase in English speculation and practice in the sphere of ethics and politics. Throughout his life he was a great antiseptic influence in English thought upon education and the functions of the State. M E S

**HYGIENE** — Hygiene (from *ὑγιεία*, hygiene, health) is usually defined as the science that treats of the prevention of disease and the preservation of health. It is especially an applied science, and, in a certain sense, an art. It aims, in the words of a modern writer, "to make growth more perfect, life more vigorous, decay less rapid, death more remote." The positive note in this definition of aims is characteristic of recent hygiene. It is no longer satisfied with the mere attempt to prevent disease, but it emphasizes especially the need of normal healthful development and the acquisition of vigorous habits of health that shall be prophylactic against disease.

The scientific study of hygiene is recent. The attempt to practice hygiene is very old. The art of hygiene is supposed to have begun with the ancient Egyptians; and a crude mass of folk traditions representing more or less clearly the experience and superstitions of the race in regard to the preservation of health has come down to us. On account of the recency

of the scientific study, a vast amount of error is mingled with the truths of experience that have survived. But while the scientific method as applied especially to hygiene is recent, and the results are still so meager that some investigators call it the science of the future, nevertheless the same ideals and the same methods are employed here as in other parts of the field of science, and here as elsewhere the most rigorous scientific experimentation under controlled conditions and with verification of results is demanded.

The subject of hygiene naturally divides into personal and public hygiene. Hygiene in a broad sense includes also the study of conditions that favor the healthful development of the human species (eugenics); the conditions affecting the health, preservation, and development of special races (racial hygiene); and the conditions that favor the healthful development of human society (social hygiene).

Public hygiene has many divisions. on the one hand, sanitation as regards soil, water, food, air, cleanliness in general, protection from disease, care of the dead, the defective, the feeble-minded, etc.; and on the other hand, the hygiene of occupations—military hygiene, naval hygiene, the hygiene of factories, etc. An introduction to the subject of public hygiene is given by such American textbooks as those of Bergey, Harrington, and Sedgwick, and the scope of it is shown by Weyl's great handbook. Among these various departments of public hygiene none is more important than child hygiene and school hygiene, and the whole field should interest teachers. These subjects and personal hygiene are treated below in special articles. W H B.

**HYGIENE OF GRADING.** — See GRADING, HYGIENE OF.

**HYGIENE OF INSTRUCTION.** — See HYGIENE, SCHOOL.

**HYGIENE, PERSONAL** — Personal hygiene consists of two important parts, somatic hygiene and mental hygiene. On account of the great individual differences in strength, endurance, ability to work and to resist disease, the problem in both these fields must be an individual one. The solution is of vital importance, especially for the teacher, not only for the preservation of the teacher's own health, but for the right performance of one's professional work and to enable one to set a proper example before one's pupils. Mental hygiene is quite as important for the teacher as somatic hygiene, and the teachings of mental hygiene and the hygiene of instruction are so important for sound education that for pedagogical as well as hygienic reasons the teacher cannot ignore them.

The subject has also important social aspects. In its wider sense personal hygiene is the very basis of disease prevention and health preservation. All plans for community or national freedom from disease must rest upon and depend upon the care with which the individual members of society settle their problems in personal hygiene. If every member of any given social unit would persistently apply his rights of franchise in favor of more stringent and effective laws of hygiene and sanitation, the problems of personal hygiene would be far easier. The difficulties of personal health control are largely difficulties which are of a community origin. The transgressions of one member of a community are visited upon the lives of his innocent fellow citizens. Equity in matters of this kind is secured only through law backed by strong popular sentiment. Then, if every member of any given social unit is protected from hygienic or sanitary injury inflicted by his fellow citizens, he may organize his policy of personal health control with every prospect of success. Under such circumstances it would be possible to develop a community in which each member practiced intelligent habits of bodily nourishment, supervising the food he would eat, the food he would drink, and the food he would breathe; intelligent habits of excretion; intelligent habits of exercise, in-

telligent habits of rest, and intelligent habits of cleanliness. Men of such habits are men of health, men of strength, men of efficiency. A community or a nation with such habits would have solved the problem of prevention of disease and have conserved its resources in terms of human life, human happiness, and human prosperity, with all that such conservation means economically, socially, and politically.

Another very important relationship of personal hygiene is its relationship to intellectual efficiency. The uncorrected, incapacitating, remediable physical defects of school children, the time lost through absences due to preventable disease, the paralyses and other organic degenerations following the preventable diseases and leaving chronic incurable conditions obstructive of further mental development and destructive of that already attained, the disturbed home conditions producing nervous strain, poverty, undernourishment, and lowered resistance, following parental disease or death, are all samples of serious avoidable and preventable conditions affecting the intellectual activities of school children. If the personal hygiene of school children and the personal hygiene of the communities in which they live were what they ideally ought to be and what they could be, these destructive conditions could not exist.

Furthermore, the aggressively healthy child is the most efficient child academically as well as physically considered. The teacher that is working with sound healthy minds will secure larger educational results than under less normal conditions. This fact is effectively proven by the experiences of our open-air schools, the introduction of school lunches, the progress of pupils who have been relieved of incapacitating physical defects, and the studies of men who have compared schools and school children representing various types of physiological health.

**The Scope of Personal Hygiene** — In its narrower sense, personal hygiene has been construed as including only those physiological and anatomical and very intimate personal relationships and habits which are obviously personal. Such a conception would bring the following topics under the heading of "Personal Hygiene". Care of the clothing, skin, scalp, nails, eyes, ears, nose, teeth, mouth, throat, heart, lungs, alimentary canal, genitourinary organs, bones, joints, brain and nervous system, food, water, ventilation, tea, coffee, alcohol, and tobacco. In some texts "first aid to the injured" (*q.v.*) is included.

A wider construction of the scope of personal hygiene includes everything that bears upon the health of the human body. (See **HYGIENE, TEACHING OF**.) Such a scope would include the various subtopics connected directly and indirectly with the following subjects. Bodily nourishment, including food,

water, and air, the excretions, exercise, rest; the influence of abnormal conditions on health (*e.g.* defective vision, bad teeth, adenoids, constipation), the influence of certain habits on health (*e.g.* rapid eating, bad habits of vision, smoking, drug habits, sexual habits, etc.), the causes of disease; the carriers of disease, our defenses against disease, and the nature of our common diseases.

Personal hygiene considered from this point of view would be rational and comprehensive. Its relationship to sex hygiene (*q.v.*) domestic hygiene, school hygiene, medical inspection (*q.v.*), school nursing, community hygiene, industrial hygiene, military, naval, and national hygiene is obvious. These special divisions of hygiene are important because they represent personal hygiene under special conditions. The hygiene of all society and of all the enterprises of society depends upon the hygiene of the individual. On the other hand, the individual is more than powerless unless society as a whole stands for such regulations and such customs as will make possible, easy, and practical the application of the laws of health.

**HYGIENE, SCHOOL** — School hygiene, one of the most important departments of public hygiene, is concerned with the conditions of health in the schoolroom and the sanitation of the school surroundings. During the last fifty years the scientific method has been more and more employed in this field, and a solid nucleus of scientific fact has been collected. A rich literature has been contributed in the form of articles not only in the special periodicals devoted to the subject, in reports, proceedings of societies, and the like, but in the archives of Hygiene, of Medicine, Physics, Psychology,

Anthropology, and even in those of Architecture and Engineering, as well as in the educational journals. The three large German handbooks, by Baginsky and Janke, Burgerstein and Netolitzky, and Eulenberg and Bach, show the scope of the work already done; and the little textbooks by Shaw, Kotelmann, and others, furnish convenient compends of the elementary facts and principles.

The history of the development of the subject is interesting, but can be briefly told. The ancient Greeks, with their emphasis upon physical training in early education and the important treatises by Philostratus, Lucian, and Oribasius, were pioneers in school hygiene. While in the Middle Ages hygiene was largely ignored by writers and teachers, with the Renaissance came a new interest in health and physical development. Vittorino made play and hardy nurture a prominent feature in his school. Luther emphasized the need of physical exercise. Comenius insisted on spacious classrooms, playgrounds, physical training, sound health as a condition of a sound mind, and the adaptation of instruction to the pupil's stage of development. The Jesuits practiced hygiene in their schools, and the reformers like Locke, Rousseau, and Basedow preached it. School hygiene in the modern sense began with the founders of gymnastics, — Guts Muths, Jahn, and Ling, — and with the work of physicians like Frank and Lorinser, and was placed upon a solid foundation by the special studies of a long line of investigators from Lang, Zweiz, Fahrner, Von Pettenkoffer, Cohn, and Barnard, down to the present time.

School hygiene draws its facts from many sources, and naturally it overlaps other related subjects, such as general hygiene, sanitary engineering, medicine, child hygiene, etc. The subject naturally divides into three parts — the construction and sanitation of the school-house, the hygiene of the school child, and the hygiene of instruction. All of these are, of course, ultimately concerned with the health of the child, but the classification is a convenient one. The aim of all of these is positive, the development in the school child of habits of healthful activity. Especially and directly is this true of the last two divisions — the hygiene of the school child and the hygiene of instruction.

**Hygiene of the School Child** — Child hygiene in an important sense is a special subject because the child's body differs from that of the adult. The hygiene of the school child demands special consideration because of the special work required in the school. It is based upon the character of the child's body and the laws of growth, and it seeks to determine the needs and to avoid the dangers of each stage of development. Hence among the important contributions to school hygiene in the last twenty-five years have been many scientific studies of growth and development, of

the diseases and abnormalities of school children, and of the defects of the various sense organs. Thus the relation of physical development to intelligence, the incidence of disease by years, by grades, by seasons, by months of the school year, the relation of defects to school progress, etc. Methods of detecting and controlling contagious diseases have been investigated, and certain important correlations have already been established. By the introduction of health inspection into the public schools in recent years not only is the importance of school hygiene emphasized, but a large amount of valuable material for the study of the subject is being collected. The school should be made the most important factor in public hygiene; for in it practically all the children are collected, and conditions can be controlled in the interests of health. The prime importance of this part of school hygiene for the teacher is obvious. (See **CONTAGIOUS DISEASES; EAR, EXCLUSION FROM SCHOOL, EYE; MEDICAL INSPECTION, etc.**)

**Hygiene of Instruction** — While this department of school hygiene may be said to have begun with the Greeks and been treated by Comenius, it has been developed only in recent years. It is now so important, however, that Burgerstein devotes some four hundred pages to it in the second edition of his handbook, and each year brings important new contributions. It emphasizes the hygienic importance of the mental habits formed by education and of the secondary effects of instruction, and it studies every educational principle and method and the matter of instruction from the point of view of hygiene. Thus each subject of instruction is considered with regard to the effect of the discipline on health. (See articles on the Hygiene of **ARITHMETIC, READING, DRAWING, SPELLING, SINGING, etc.**)
